Introduction

The Shorter REP has emerged out of our experience with *Concise REP*, the first one-volume distillation of the original ten-volume *Routledge Encyclopedia of Philosophy* published in 1998. *Concise REP*, appearing in 2000, was composed of the initial, introductory or summary sections of each of the 2,054 entries contained in the parent work, which it therefore matched everywhere for breadth, but hardly anywhere for depth. By virtue of its sheer range *Concise REP* fulfilled a need, but we have heard from users and reviewers who would evidently have preferred more depth – and would have been willing, we must presume, to sacrifice some breadth to get it. Thinking about this valuable feedback quickly led to a different conception of a single-volume reduction of the encyclopedia, that now embodied in *The Shorter REP*. By excising much of the more recondite material we have made it possible for a considerable number of entries on the more central and sought-after topics to be included in their entirety, even though in some cases that meant as much as 15,000 words or more.

The Shorter REP accordingly contains just 957 entries, but of these 119 are republished here in their full original length, and marked out by bold typeface in the headwords at the top of the page. The reader will find substantial essays on all the major figures of the Western philosophical tradition, likewise on all major topics and those we judged to be of most help to a student readership. Further, we have reprinted in full all the 'Signpost' entries, in which members of the original team of specialist subject editors surveyed in brief, usually in about 2,000 words, their specialist field. There are twenty-four of these, instantly recognisable from their light-grey background; taken together they offer the reader a highly informative outline sketch of pretty much the whole of philosophy, Latin American, African, Jewish, Arabic, Russian, Indian and East-Asian thought all included. *The Shorter REP* is unashamedly 'Western' in its emphasis, being designed to suit the needs of undergraduate philosophy students and the courses they are most likely to encounter. But so far as the stringencies of a single volume allow it retains the spirit of inclusivity and comprehensiveness that was such a feature of its ten-volume ancestor. Nowhere is the 'Signpost' the only entry allotted to its area – in every case there are at least two others.

The inclusion of so many complete entries has had another welcome effect, that of allowing us to do a little more justice to at least some of the encyclopedia's most eminent authors: Richard Rorty, Bernard Williams, Dagfinn Føllesdal, Tim Scanlon, Philip Kitcher, Timothy Williamson, Onora O'Neill, Gary Gutting, Anthony Appiah, Frank Jackson, Michael Friedman, Dan Garber, Malcolm Budd, Terry Irwin and the list runs on, though I have to stop, apologetically, somewhere. Entries by all these and many others appear in their original shape, unabridged.

The Shorter REP is not just a selective rearrangement of the old material. Admittedly hardly anything has been rewritten specifically for *The Shorter REP*, just two very short entries in fact, but it nevertheless contains a good deal that is new when compared with the original 1998 publication. Any slight suggestion of paradox is easily dispelled: since October 2000 the Routledge Encyclopedia has been available on the Internet as *REP Online*, in which form it has seen additions (at present towards 100 new entries) and a number (now approaching thirty) of updates and revisions, concentrating on entries near the top of our list of user-statistics. Some of the revised entries embody only minor changes, perhaps the mention of a recent book or article, others differ much more from their first versions, as for instance *Wittgenstein* (by Jane Heal), which as well as various smaller adjustments now has a whole new section on recent interpretative controversy about Wittgenstein's *Tractatus*. In one absolutely central case, of obvious prime interest to students, we have a completely rewritten replacement entry: this is *David Hume*, by Don Garrett. All this new material for *REP Online* was available to us as we made our selections for *The Shorter REP*, and a good deal of it is now to be found here. Some further examples of revisions now in full in *The Shorter REP* as well as *REP Online* are *Plato* (Malcolm Schofield), *Socrates* (John

Cooper), *Stoicism* and *Epicureanism* (both David Sedley), *Hobbes* (Tom Sorrell), *Justice* (Brian Barry and Matt Matravers), *Kant* (Paul Guyer), *Foucault* (Gary Gutting), *Heidegger* (Thomas Sheehan), *Quine* (Alex Orenstein), *Feminism* (Susan James), *Existentialism* (Charles Guignon), *Infinity* (Adrian Moore), and *Democracy* (Ross Harrison). In addition, as many as nineteen of the new entries, hitherto available only on the Internet in *REP Online*, are to be found here in their shorter form: *Innateness in ancient philosophy; Prolēpsis; Technē; Telos; Magic; More, Thomas; Eclecticism; Fourier, Charles; de Maistre, Joseph; Novalis; Apel, Karl-Otto; Cloning; Normativity; Globalization; Sustainability; Beccaria; Causation in the law; Justice, corrective;* and *Simulation theory*. Besides this, two new entries are printed here in full. One is *Painting, aesthetics of* (Robert Hopkins); the other is a new 'Signpost' entry: *Nineteenth-century philosophy* by Robert Stern. I hope that as General Editor I may be allowed to attach, to the second of these in particular, my personal recommendation. The nineteenth century seems to me too little studied and understood in English-speaking philosophical circles. Too few of us could give a coherent sketch of its currents and tensions, its emergence from the eighteenth century and its legacy to the twentieth. Stern can, so this new Signpost entry, together with our substantial coverage of nineteenth century philosophers, will help – if readers want it to.

In a work of this kind bibliographical information can be very costly in terms of space and has to be kept to a minimum. Nevertheless, our treatment of the bibliographies, or 'Further reading', also allows scope for revision or updating. We invited the authors of the 119 main entries (i.e. those which appear in full) to provide titles and authors of just two or three works likely to be helpful to the reader, not of course necessarily drawn from their original listing. Any especially suitable works published since the middle of 1997 – when the ten volume REP finally had to raise its drawbridge against any further text – thus had at least the chance to be considered for inclusion. The response was superb – we are delighted to be able to include over 80 revised Further reading sections.

So much for inclusion; what of the less happy matter of exclusion? Such an enterprise is bound to leave some regrets on this score in the minds of the editorial team, some disappointment amongst authors and some unfulfilled expectations amongst readers. One volume, if it is to have a readable print-size and paper thick enough not to be transparent, can be crammed so full and no fuller. Complete REP entries are on average nine times as long as their short versions, so every one had to be felt to justify its status. The thought that by printing one of the biggest entries in full we were committing space sufficient for perhaps thirty or forty short ones focussed the mind; the regrettable fact that, for example, *Schopenhauer*, and *Peirce* appear only in their shortened forms has a lot to do with that consideration. But the thinking behind such decisions often had a positive aspect as well. Entries were in competition for space not just with other topics, but also with their own shorter versions; and where this was especially well written and rich in information it on several occasions prevailed, even when the subject, in itself, might well have suggested full-length treatment. Leaving nine-tenths of an author's work out does seem a backhanded way of showing gratitude, but grateful we are, and we hope that future readers have cause to be so too.

List of entries and contributors

Below is a complete list of entries and contributors in the order in which they appear in *The Shorter Routledge Encyclopedia of Philosophy.*

A

A POSTERIORI

A prominent term in theory of knowledge since the seventeenth century, 'a posteriori' signifies a kind of knowledge or justification that depends on evidence, or warrant, from sensory experience. A posteriori truth is truth that cannot be known or justified independently of evidence from sensory experience, and a posteriori concepts are concepts that cannot be understood independently of reference to sensory experience. A posteriori knowledge contrasts with a priori knowledge, knowledge that does not require evidence from sensory experience. A posteriori knowledge is empirical, experience-based knowledge, whereas a priori knowledge is non-empirical knowledge. Standard examples of a posteriori truths are the truths of ordinary perceptual experience and the natural sciences; standard examples of a priori truths are the truths of logic and mathematics. The common understanding of the distinction between a posteriori and a priori knowledge as the distinction between empirical and non-empirical knowledge comes from Kant's *Critique of Pure Reason* (1781/1787).

PAUL K. MOSER

A PRIORI

An important term in epistemology since the seventeenth century, 'a priori' typically connotes a kind of knowledge or justification that does not depend on evidence, or warrant, from sensory experience. Talk of a priori truth is ordinarily shorthand for talk of truth knowable or justifiable independently of evidence from sensory experience; and talk of a priori concepts is usually talk of concepts that can be understood independently of reference to sensory experience. A priori knowledge contrasts with a posteriori knowledge, knowledge requiring evidence from sensory experience. Broadly characterized, a posteriori knowledge is empirical, experience-based knowledge, and a priori knowledge is non-empirical knowledge. Standard examples of a priori truths are the truths of mathematics, whereas standard examples of a posteriori truths are the truths of the natural sciences.

ABELARD, PETER (1079–1142)

Among the many scholars who promoted the revival of learning in Western Europe in the early twelfth century, Abelard stands out as a consummate logician, a formidable polemicist and a champion of the value of ancient pagan wisdom for Christian thought. Although he worked within the Aristotelian tradition, his logic deviates significantly from that of Aristotle, particularly in its emphasis on propositions and what propositions say. According to Abelard, the subject matter of logic, including universals such as genera and species, consists of linguistic expressions, not of the things these expressions talk about. However, the objective grounds for logical relationships lie in what these expressions signify, even though they cannot be said to signify any things. Abelard is, then, one of a number of medieval thinkers, often referred to in later times as 'nominalists', who argued against turning logic and semantics into some sort of science of the 'real', a kind of metaphysics. It was Abelard's view that logic was, along with grammar and rhetoric, one of the sciences of language.

In ethics, Abelard defended a view in which moral merit and moral sin depend entirely on whether one's intentions express respect for the good or contempt for it, and not at all on one's desires, whether the deed is actually carried out, or even whether the deed is in fact something that ought or ought not to be done.

Abelard did not believe that the doctrines of Christian faith could be proved by logically

compelling arguments, but rational argumentation, he thought, could be used both to refute attacks on Christian doctrine and to provide arguments that would appeal to those who were attracted to high moral ideals. With arguments of this latter sort, he defended the rationalist positions that nothing occurs without a reason and that God cannot do anything other than what he does do.

ABSOLUTE, THE

The expression 'the Absolute' stands for that (supposed) unconditioned reality which is either the spiritual ground of all being or the whole of things considered as a spiritual unity. This use derives especially from F.W.J. Schelling and G.W.F. Hegel, prefigured by J.G. Fichte's talk of an absolute self which lives its life through all finite persons. In English-language philosophy it is associated with the monistic idealism of such thinkers as F.H. Bradley and Josiah Royce, the first distinguishing the Absolute from God, the second identifying them.

T.L.S. SPRIGGE

ABSOLUTISM

The term 'absolutism' describes a form of government in which the authority of the ruler is subject to no theoretical or legal constraints. In the language of Roman law – which played a central role in all theories of absolutism – the ruler was *legibus solutus*, or 'unfettered legislator'. Absolutism is generally, although not exclusively, used to describe the European monarchies, and in particular those of France, Spain, Russia and Prussia, between the middle of the sixteenth century and the end of the eighteenth. But some form of absolutism existed in nearly every European state until the late eighteenth century. There have also been recognizable forms of absolute rule in both China and Japan.

As a theory absolutism emerged in Europe, and in particular in France, in the late sixteenth and early seventeenth centuries, in response to the long Civil Wars between the Crown and the nobility known as the Wars of Religion. In the late eighteenth century, as the reform movement associated with the Enlightenment began to influence most European rulers, a form of so-called 'enlightened absolutism' (or sometimes 'enlightened despotism') emerged. In this the absolute authority of the ruler was directed not towards enhancing the power of the state, but was employed instead for advancing the welfare of the subjects.

ABSTRACT OBJECTS

The central philosophical question about abstract objects is: Are there any? An affirmative answer – given by Platonists or Realists – draws support from the fact that while much of our talk and thought concerns concrete (roughly, spatiotemporally extended) objects, significant parts of it appear to be about objects which lie outside space and time, and are therefore incapable of figuring in causal relationships. The suggestion that there really are such further non-spatial, atemporal and acausal objects as numbers and sets often strikes Nominalist opponents as contrary to common sense. But precisely because our apparent talk and thought of abstracta encompasses much – including virtually the whole of mathematics – that seems indispensable to our best attempts to make scientific sense of the world, it cannot be simply dismissed as confused gibberish. For this reason Nominalists have commonly adopted a programme of reductive paraphrase, aimed at eliminating all apparent reference to and quantification over abstract objects. In spite of impressively ingenious efforts, the programme appears to run into insuperable obstacles.

The simplicity of our initial question is deceptive. Understanding and progress are unlikely without further clarification of the relations between ontological questions and questions about the logical analysis of language, and of the key distinction between abstract and concrete objects. There are both affinities and, more importantly, contrasts between traditional approaches to ontological questions and more recent discussions shaped by ground-breaking work in the philosophy of language initiated by Frege. The importance of Frege's work lies principally in two insights: first, that questions about what kinds of entity there are cannot sensibly be tackled independently of the logical analysis of language; and second, that the question whether or not certain expressions should be taken to have reference cannot properly be separated from the question whether complete sentences in which those expressions occur are true or false.

ACTION

Philosophical study of human action owes its importance to concerns of two sorts. There are concerns addressed in metaphysics and philosophy of mind about the status of reasoning beings who make their impact in the natural causal world, and concerns addressed in ethics and legal philosophy about human freedom and responsibility. 'Action theory' springs from concerns of both sorts; but in the first instance it attempts only to provide a detailed account that may help with answering the metaphysical questions.

Action theorists usually start by asking 'How are actions distinguished from other events?'. For there to be an action, a person has to do something. But the ordinary 'do something' does not capture just the actions, since we can say (for instance) that breathing is something that everyone does, although we don't think that breathing in the ordinary way is an action. It seems that purposiveness has to be introduced – that someone's *intentionally* doing something is required.

People often do the things they intentionally do by moving bits of their bodies. This has led to the idea that 'actions are bodily movements'. The force of the idea may be appreciated by thinking about what is involved in doing one thing by doing another. A man piloting a plane might have shut down the engines by depressing a lever, for example; and there is only one action here if the depressing of the lever was (identical with) the shutting down of the engines. It is when identities of this sort are accepted that an action may be seen as an event of a person's moving their body: the pilot's depressing of the lever was (also) his moving of his arm, because he depressed the lever by moving his arm.

But how do bodies' movings – such events now as his arm's moving – relate to actions? According to one traditional empiricist account, these are *caused* by *volitions* when there are actions, and a volition and a body's moving are *alike* parts of the action. But there are many rival accounts of the causes and parts of actions and of movements. And volitional notions feature not only in a general account of the events surrounding actions, but also in accounts that aim to accommodate the *experience* that is characteristic of agency.

JENNIFER HORNSBY

ADORNO, THEODOR WIESENGRUND (1903–69)

Philosopher, musicologist and social theorist, Theodor Adorno was the philosophical architect of the first generation of Critical Theory emanating from the Institute for Social Research in Frankfurt, Germany. Departing from the perspective of more orthodox Marxists, Adorno believed the twin dilemmas of modernity – injustice and nihilism – derived from the abstractive character of Enlightenment rationality. In consequence, he argued that the critique of political economy must give way to a critique of Enlightenment, instrumental reason.

Identity thinking, as Adorno termed instrumental rationality, abstracts from the sensory, linguistic and social mediations which connect knowing subjects to objects known. In so doing, it represses what is contingent, sensuous and particular in persons and nature. Adorno's method of negative dialectics was designed to rescue these elements from the claims of instrumental reason. Adorno conceded, however, that all this method could demonstrate was that an abstract concept did not exhaust its object. For a model of an alternative grammar of reason and cognition Adorno turned to the accomplishments of artistic modernism. There, where each new work tests and transforms the very idea of something being a work of art, Adorno saw a model for the kind of dynamic interdependence between mind and its objects that was required for a renewed conception of knowing and acting.

J.M. BERNSTEIN

AESTHETIC ATTITUDE

It is undeniable that there are aesthetic and non-aesthetic attitudes. But is there such a thing as *the* aesthetic attitude? What is meant by the aesthetic attitude is the particular way in which we regard something when and only when we take an aesthetic interest in it. This assumes that on all occasions of aesthetic interest the object attended to is regarded in an identical fashion, unique to such occasions; and this assumption is problematic. If an attitude's identity is determined by the features it is directed towards; if an aesthetic interest in an object is (by definition) an interest in its aesthetic qualities; and if the notion of aesthetic qualities can be explained in a uniform manner; then there is a unitary aesthetic attitude, namely an interest in an item's aesthetic qualities. But this conception of the aesthetic attitude would be unsuitable for achieving the main aim of those who have posited the aesthetic attitude. This aim is to provide a definition of the aesthetic, but the aesthetic attitude, understood as any attitude focused upon an object's aesthetic qualities, presupposes the idea of the aesthetic, and cannot be used to analyse it. So the question is whether there is a characterization of the aesthetic attitude that describes its nature without explicitly or implicitly relying on the concept of the aesthetic. There is no good reason to suppose so.

Accordingly, there is no such thing as the aesthetic attitude, if this is an attitude that is both necessary and sufficient for aesthetic interest and that can be characterized independently of the aesthetic.

See also: Aesthetic concepts

MALCOLM BUDD

AESTHETIC CONCEPTS

Aesthetic concepts are the concepts associated with the terms that pick out aesthetic properties referred to in descriptions and evaluations of experiences involving artistic and aesthetic objects and events. The questions (epistemological, psychological, logical and metaphysical) that have been raised about these properties are analogous to those raised about the concepts.

In the eighteenth century, philosophers such as Edmund Burke and David Hume attempted to explain aesthetic concepts such as beauty empirically, by connecting them with physical and psychological responses that typify individuals' experiences of different kinds of objects and events. Thus they sought a basis for an objectivity of personal reactions. Immanuel Kant insisted that aesthetic concepts are essentially subjective (rooted in personal feelings of pleasure and pain), but argued that they have a kind of objectivity on the grounds that, at the purely aesthetic level, feelings of pleasure and pain are universal responses.

In the twentieth century, philosophers have sometimes returned to a Humean analysis of aesthetic concepts via the human faculty of taste, and have extended this psychological account to try to establish an epistemological or logical uniqueness for aesthetic concepts. Many have argued that although there are no aesthetic laws (for example, 'All roses are beautiful,' or 'If a symphony has four movements and is constructed according to rules of Baroque harmony, it will be pleasing') aesthetic concepts none the less play a meaningful role in discussion and disputation. Others have argued that aesthetic concepts are not essentially distinguishable from other types of concepts.

Recently theorists have been interested in ways that aesthetic concepts are context-dependent – constructed out of social mores and practices, for example. Their theories often deny that aesthetic concepts can be universal. For example, not only is there no guarantee that the term 'harmony' will have the same meaning in different cultures: it may not be used at all.

MARCIA EATON

AESTHETICS

Introduction

Aesthetics owes its name to Alexander Baumgarten who derived it from the Greek *aisthanomai*, which means perception by means of the senses. As the subject is now understood, it consists of two parts: the philosophy of art, and the philosophy of the aesthetic experience and character of objects or phenomena that are not art. Non-art items include both artefacts that possess aspects susceptible of aesthetic appreciation, and phenomena that lack any traces of human design in virtue of being products of nature, not humanity. How are the two sides of the subject related: is one part of aesthetics more fundamental than the other? There are two obvious possibilities. The first is that the philosophy of art is basic, since the aesthetic appreciation of anything that is not art is the appreciation of it as if it were art. The second is that there is a unitary notion of the aesthetic that applies to both art and non-art; this notion defines the idea of aesthetic appreciation as disinterested delight in the immediately perceptible properties of an object for their own sake; and artistic appreciation is simply aesthetic appreciation of works of art. But neither of these possibilities is plausible.

The first represents the aesthetic appreciation of nature as essentially informed by ideas intrinsic to the appreciation of art, such as style, reference and the expression of psychological states. But in order for that curious feeling, the experience of the sublime – invoked, perhaps, by the immensity of the universe as disclosed by the magnitude of stars visible in the night sky (see Sublime, the) – to be aesthetic, or for you to delight in the beauty of a flower, it is unnecessary for you to imagine these natural objects as being works of art. In fact, your appreciation of them is determined by their lack of features specific to works of art, and perhaps also by their possession of features available only to aspects of nature (see Nature, aesthetic appreciation of).

The second fails to do justice to the significance for artistic appreciation of various features of works of art that are not immediately perceptible, such as a work's provenance and its position in the artist's oeuvre. A more accurate view represents the two parts of the subject as being related to each other in a looser fashion than either of these positions recognizes, each part exhibiting variety in itself, the two being united by a number of common issues or counterpart problems, but nevertheless manifesting considerable differences in virtue of the topics that are specific to them. In fact, although some issues are common to the two parts, many are specific to the philosophy of art and a few specific to the aesthetics

of non-art objects. Moreover, not every object of aesthetic appreciation falls neatly on one side or the other of the art–non-art distinction, so that appreciation sometimes involves an element of both of artistic and non-artistic appreciation (see ENVIRONMENTAL AESTHETICS).

Both works of art and other objects can possess specifically aesthetic properties, such as beauty and gracefulness. If they do possess properties of this sort, they will also possess properties that are not specifically aesthetic, such as size and shape. And they will be susceptible of aesthetic and non-aesthetic appreciation, and subject to aesthetic and non-aesthetic judgments. What distinguishes an item's aesthetic from its non-aesthetic properties and what faculties are essential to detecting aesthetic properties (see AESTHETIC CONCEPTS)? What is the nature of aesthetic appreciation? It has often been thought that there is a particular attitude that is distinctive of aesthetic appreciation: you must adopt this attitude in order for the item's aesthetic properties to be manifest to you, and if you are in this attitude you are in a state of aesthetic contemplation (see AESTHETIC ATTITUDE). This suppositious attitude has often been thought of as one of disinterested contemplation focused on an item's intrinsic, non-relational, immediately perceptible properties. But perhaps this view of aesthetic interest as disinterested attention is the product of masculine bias, involving the assumption of a position of power over the observed object, a reflection of masculine privilege, an expression of the 'male gaze'. Another idea is that awareness of an object's aesthetic properties is the product of a particular species of perception, an idea which stands in opposition to the claim that this awareness is nothing but the projection of the observer's response onto the object.

An object's beauty would appear to be a relational, mind-dependent property – a property it possesses in virtue of its capacity to affect observers in a certain manner. But which observers and what manner? And can attributions of beauty, which often aspire to universal interpersonal validity, ever attain that status (see BEAUTY)? The great German philosopher Immanuel Kant presented a conception of an aesthetic judgment as a judgment that must be founded on a feeling of pleasure or displeasure; he insisted that a pure aesthetic judgment about an object is one that is unaffected by any concepts under which the object might be seen; and he tried to show that the implicit claim of such a judgment to be valid for everyone is justified. But how acceptable is his conception of an aesthetic judgment and how successful is his attempted justification of the claims of pure aesthetic judgments (see KANT, I. §12)?

1 Aesthetics of art

Those questions that are specific to the philosophy of art are of three kinds: ones that arise only within a particular art form or set of related arts (perhaps arts addressed to the same sense), ones that arise across a number of arts of heterogeneous natures, and ones that are entirely general, necessarily applying to anything falling under the mantle of art.

Here are some of the most salient facts about art. Not everything is art. Artists create works of art, which reflect the skills, knowledge and personalities of their makers, and succeed or fail in realizing their aims. Works of art can be interpreted in different ways, understood, misunderstood or baffle the mind, subjected to analysis, and praised or criticized. Although there are many kinds of value that works of art may possess, their distinctive value is their value as art. The character of a work of art endows it with a greater or lesser degree of this distinctive value.

Accordingly, the most fundamental general question about art would seem to be: what is art? Is it possible to distinguish art from non-art by means of an account that it is definitive of the nature of art, or are the arts too loosely related to one another for them to possess an essence that can be captured in a definition (see ART, DEFINITION OF)? Whatever the answer to this question may be, another entirely general issue follows hard on its heels. It concerns the ontology of art, the kind of thing a work of art is. Do some works of art fall into one ontological category (particulars) and some into another (types) or do they all fall within the same category (see ART WORKS, ONTOLOGY OF)? And a number of other important general questions quickly arise. What is a work's artistic value and which aspects of a work are relevant to or determine this value? Is the value of a work of art, considered as art, an intrinsic or an extrinsic feature of it? Is it determined solely by the work's form or by certain aspects of its content – its truth or its moral sensitivity, for example? Can judgments about a work's artistic value justifiably lay claim to universal agreement or are they merely expressions of subjective preferences? And how is a work's artistic value related to, and how important is it in comparison with, other kinds of value it may possess (see ART, VALUE OF; FORMALISM IN ART; ART AND TRUTH; ART AND MORALITY; SCHILLER, J.C.F.)? What is required to detect the critically relevant properties of artworks, over and above normal perceptual and intellectual powers, and how can judgments that attribute such properties be supported (see ART CRITICISM)? What kinds of understanding are involved in artistic appreciation, and must an acceptable interpretation of a work be compatible with any other acceptable interpretation

(see ART, UNDERSTANDING OF)? In what way, if any, does the artist's intention determine the meaning or their work (see ARTIST'S INTENTION)? What is an artist's style and what is its significance in the appreciation of the artist's work?

2 Aesthetics and the arts

One question that arises only for a small set of art forms concerns the nature of depiction. It might be thought that the analysis of the nature of depiction has no special importance within the philosophy of art, for pictorial representation is just as frequent outside as inside art. But this overlooks the fact that real clarity about the ways in which pictures can acquire value as art must be founded on a sophisticated understanding of what a picture is and the psychological resources needed to grasp what it depicts. So what is it for a surface to be or contain a picture of an object or state of affairs? Must the design on the surface be such as to elicit a certain species of visual experience, and must the function of the means by which the pattern was produced, or the intention of the person who created it, be to replicate features of the visible world? Or is a picture a member of a distinctive kind of symbol system, which can be defined without making use of any specifically visual concepts (see DEPICTION)? Another question that has a limited application concerns the distinctive nature and value of a particular artistic genre, the response it encourages from us, and the insight into human life it displays and imparts. For example, whereas a comedy exploits our capacity to find something funny, a tragedy engages our capacity to be moved by the fate of other individuals, and erotic art aims to evoke a sexual reaction; and this difference in the emotional responses at the hearts of the genres goes hand in hand with the different aspects of human life they illuminate (see COMEDY; EMOTION IN RESPONSE TO ART; HUMOUR; TRAGEDY).

Questions about the individual natures and possibilities of the various arts include some that are specific to the particular art and some that apply also to other arts. On the one hand, relatively few art forms (architecture and pottery, for example) are directed to the production of works that are intended to perform non-artistic functions, or are of a kind standardly used for utilitarian purposes, and, accordingly, the issue of the relevance to its artistic value of a work's performing, or presenting the appearance of performing, its intended non-artistic function satisfactorily is confined to such arts (see ARCHITECTURE, AESTHETICS OF). Again, only in some arts does a spectator witness a performance of a work, so that issues about a performer's contribution to the interpretation of a work or about the evaluation of different performances of the same work are limited to such arts. And since only some works of art (novels, plays and films, for example) tell a story, and only some refer to fictional persons or events, questions about the means by which a story is told or how references to fictional objects should be understood have a restricted application within the arts (see NARRATIVE; FICTIONAL ENTITIES). On the other hand, most, if not all, arts allow of works within their domain being correctly perceived as being expressive of psychological states, and, accordingly, give rise to the question of what it is for a work to be expressive of such a condition (see ARTISTIC EXPRESSION). But the means available within the different arts for the expression of psychological states are various: poetry consists of words, dance exploits the human body, and instrumental music uses nothing other than sounds. And these different artistic media impose different limits on the kinds of state that can be expressed by works of art, the specificity of the states, and the significance within an art of the expressive aspects of its products (see GURNEY, E.). Furthermore, it is a general truth about the various arts, rather than one special to expression, that what can be achieved within an art is determined by the nature of the medium on which the art is based. Accordingly, an adequate philosophy of art must investigate the variety of such media and elucidate the peculiar advantages they offer and the limitations they impose (see FILM, AESTHETICS OF; HANSLICK, E.; LANGER, S.K.K.; LESSING, G.E.; MUSIC, AESTHETICS OF; OPERA, AESTHETICS OF; PAINTING, AESTHETICS OF; PHOTOGRAPHY, AESTHETICS OF; POETRY).

AESTHETICS AND ETHICS

The contrast between ethical and aesthetic judgments, which has provided a good deal of the subject-matter of aesthetics, stems largely from Immanuel Kant's idiosyncratic view of morality as

a series of imperatives issued in accordance with the dictates of practical reason, while for him judgments of taste are based on no principles. This has led even non-Kantians to argue that aesthetic judgments are primarily concerned, as is art itself, with uniqueness, while morality has mainly to do with repeatable actions. This tends to separate art from other human activities, a separation which was encouraged by the collection of useless items by ‘connoisseurs’, who took over as their vocabulary of appreciation the traditional language of religious contemplation. This viewpoint has been attacked passionately by idealist aestheticians, who claim that art is a heightening of the common human activity of expressing emotions, to the point where they are experienced and rendered lucidly, as they rarely are in everyday life. Marxist aestheticians, whose roots lie in the same tradition as idealists, argue that art is inherently political, and that the realm of ‘pure aesthetic experience’ is chimerical. Meanwhile the analytic tradition in aesthetics has spent much effort amplifying Kant-style positions, without taking into account their historical conditioning. There is a tendency to contrast the activities of the moralist, prescribing courses of action, with that of the critic, whose only job can be to point to the unrepeatable features which constitute a work of art.

AFFIRMATIVE ACTION

The term ‘affirmative action’ originated in the USA under President Kennedy. Originally it was designed to ensure that employees and applicants for jobs with government contractors did not suffer discrimination. Within a year, however, ‘affirmative action’ was used to refer to policies aimed at compensating African-Americans for unjust racial discrimination, and at improving their opportunities to gain employment. An important implication of this shift was that affirmative action came to mean preferential treatment.

Preferential treatment was later extended to include women as well as other disadvantaged racial and ethnic groups. The arguments in favour of preferential treatment can be usefully classified as backward-looking and forward-looking. Backward-looking arguments rely on the claim that preferential treatment of women and disadvantaged racial minorities compensates these groups or the members for the discrimination and injustices they have suffered. Forward-looking arguments rely on their claim that preferential treatment of women and disadvantaged racial minorities will help to bring about a better society.

There has been much criticism of both types of argument. The most common accusation is that preferential treatment is reverse discrimination. Other criticisms are based around who exactly should be compensated, by what means and to what extent, and at whose cost. Finally, there is the fear of the unknown consequences of such action. Arguments have been forwarded to try and solve such difficulties, but the future of preferential treatment seems to lie in a combination of the two arguments.

AFRICAN PHILOSOPHY

Introduction

In order to indicate the range of some of the kinds of material that must be included in a discussion of philosophy in Africa, it is as well to begin by recalling some of the history of Western philosophy. It is something of an irony that Socrates, the first major philosopher in the Western tradition, is known to us entirely for oral arguments imputed to him by his student Plato. For the Western philosophical tradition is, above all else, a tradition of texts. While there are some important ancient philosophers, like Socrates, who are largely known to us through the reports of others, the tradition has developed increasingly as one which pays careful attention to written arguments. However, many of those arguments – in ethics and politics, metaphysics and epistemology, aesthetics and the whole host of other major subdivisions of the subject – concern questions about which many people in many cultures have talked and many, albeit substantially fewer, have written about outside the broad tradition of Western philosophy. The result is that while those methods of philosophy that have developed in the West through thoughtful analysis of texts are not found everywhere, we are likely to find in every human culture opinions about some of the major questions of Western philosophy. On these important questions there have been discussions in most cultures since the earliest human societies. These constitute what has sometimes been called a ‘folk-philosophy’. It is hard to say much about those opinions and discussions in places where they have not been written down. However, we are able to find some evidence of the character of these views in such areas as parts of sub-Saharan Africa where writing was introduced into oral cultures over the last few centuries.

As a result, discussions of African philosophy should include both material on some oral cultures and rather more on the philosophical work that has been done in literate traditions on the African continent, including those that have developed since the introduction of Western philosophical training there.

1 Oral cultures

Two areas of folk-philosophy have been the object of extended scholarly investigation in the late twentieth century: the philosophical psychology of people who speak the Akan languages of the west African littoral (now Ghana) and the epistemological thought of Yoruba-speaking people of western Nigeria. In both cases the folk ideas of the tradition have been addressed by contemporary speakers of the language with Western philosophical training. This is probably the most philosophically sophisticated work that has been carried out in the general field of the philosophical study of folk-philosophy in Africa. It also offers some insight into ways of thinking about both the mind and human cognition that are different from those that are most familiar within the Western tradition.

One can also learn a great deal by looking more generally at ethical and aesthetic thought, since in all parts of the continent, philosophical issues concerning evaluation were discussed and views developed before the advent of writing. Philosophical work on ethics is more developed than in aesthetics and some of the most interesting recent work in African aesthetics also focuses on Yoruba concepts which have been explored in some detail by Western philosophers. The discussion of the status of such work has largely proceeded under the rubric of the debate about ethnophilosophy, a term intended to cover philosophical work that aims to explore folk philosophies in a systematic manner. Finally, there has also been an important philosophical debate about the character of traditional religious thought in Africa.

2 Older literate traditions

Although these oral traditions represent old forms of thought, the actual traditions under discussion are not as old as the remaining African literate traditions. The earliest of these is in the writings associated with the ancient civilizations of Egypt, which substantially predate the pre-Socratic philosophers who inhabit the earliest official history of Western philosophy. The relationship between these Egyptian traditions and the beginnings of Western philosophy have been in some dispute and there is much recent scholarship on the influence of Egypt on classical Greek thought.

Later African philosophy looks more familiar to those who have studied the conventional history of Western philosophy: the literate traditions of Ethiopia, for example, which can be seen in the context of a long (if modest) tradition of philosophical writing in the horn of Africa. The high point of such writing has been the work of the seventeenth-century philosopher, Zar'a Ya'ecob. Whose work has been compared to that of Descartes.

It is also worth observing that many of the traditions of Islamic philosophy were either the product of, or were subject to the influence of, scholars born or working in the African continent in centres of learning such as Cairo and Timbuktu (see ISLAMIC PHILOSOPHY). Similarly, the work of some of the most important philosophers among the Christian Church Fathers was the product of scholars born in Africa, like St AUGUSTINE, and some was written in the African provinces of Rome.

In considering African-born philosophers, there is Anton Wilhelm Amo, who was born in what is now Ghana and received, as the result of an extraordinary sequence of events, philosophical training during the period of German Enlightenment, before returning to the Guinea coast to die in the place he was born. Amo's considerable intellectual achievements played an important part in eighteenth- and nineteenth-century polemics relating to the 'capacity of the negro'. Unfortunately, only a portion of his work has survived.

3 Recent philosophy

Most twentieth-century work in African philosophy has been carried out by African intellectuals (often interacting with scholars outside Africa) under the influence of philosophical traditions from the European countries that colonized Africa and created her modern system of education. As the colonial systems of education were different, it is helpful to think of this work as belonging to two broadly differentiated traditions, one Francophone and the other Anglophone. While it is true that philosophers in the areas influenced by French (and Francophone Belgian) colonization developed separately from those areas under British colonial control, a comparison of their work reveals that there has been a substantial cross-flow between them (as there generally has been between philosophy in the French- and English-speaking worlds). The other important colonial power in Africa was Portugal, whose commitment to colonial education

was less developed. The sole Portuguese-speaking African intellectual who made a significant philosophical contribution is Amílcar Cabral, whose leadership in the independence movement of Guinea Bissau and the Cape Verde islands was guided by philosophical training influenced by Portuguese Marxism. Cabral's influence has not been as great as that of Frantz Fanon, who was born in the French Antilles, but later became an Algerian. He was a very important figure in the development of political philosophy in Africa (and much of the Third World).

Among the most important political thinkers influenced by philosophy are Kwame Nkrumah, Kenneth Kaunda and Julius Nyerere (see African philosophy, Anglophone). Out of all the intellectual movements in Africa in the twentieth-century, the two most important ones of philosophical interest have been *négritude* and pan-Africanism (see African philosophy, Francophone).

Philosophy in Africa has changed greatly in the decades since the Second World War and, even more, as African states have gained their independence. Given the significance of the colonial legacy in shaping modern philosophical education in Africa it is not surprising that there have been serious debates about the proper understanding of what it is for a philosophy to be African. These lively debates, prevalent in the areas of African epistemology, ethics and aesthetics, are found in both Francophone and Anglophone philosophy.

AFRICAN PHILOSOPHY, ANGLOPHONE

Contemporary African philosophy is in a state of flux, but the flow is not without some watersheds. The chief reason for the flux lies in the fact that Africa, in most part, is in a state of transition from a traditional condition to a modernized one. Philosophically and in other ways, the achievement of independence was the most significant landmark in this transition. Independence from European rule (which began in Libya in 1951, followed by Sudan in 1956, Ghana in 1957 and continued to be won at a rapid pace in other parts of Africa in the 1960s) did not come without a struggle. That struggle was, of necessity, both political and cultural. Colonialism involved not only political subjection but also cultural depersonalization. Accordingly, at independence it was strongly felt that plans for political and economic reconstruction should reflect the needs not only for modernization but also for cultural regeneration. These are desiderata which, while not incompatible in principle, are difficult to harmonize in practice. The philosophical basis of the project had first to be worked out and this was attempted by the first wave of post-independence leaders. The task of devising technical philosophies cognizant of Africa's past and present and oriented to her long-term future has been in the hands of a crop of professional philosophers trained in Western-style educational institutions. Philosophical results have not been as dramatic as in the case of the political, but the process is ongoing.

The political figures that led African states to independence were not all philosophers by original inclination or training. To start with only the best known, such as Leopold Senghor of Senegal, or Kwame Nkrumah of Ghana, were trained philosophers, but others, such as Kenneth Kaunda of Zambia, brought only an educated intelligence and a good sense of their national situations to the enterprise. In all cases they were rulers enthusiastically anointed by their people to chart the new course and lead them to the promised land. An example of how practical urgency can inspire philosophical productivity can be found in the way that all these philosophers propounded blueprints for reconstruction with clearly articulated philosophical underpinnings. Circumstantial necessity, then, rather than Platonic selection made these leaders philosopher-kings. It is significant, also, to note that all the leaders mentioned (and the majority of their peers) argued for a system of socialism deriving from their understandings of African traditional thought and practice, and from their perceptions of the imperatives generated by industrialization, such as it had been. Concern with this latter aspect of the situation led to some flirtation and even outright marriage with Marxism. But, according to the leaders concerned, the outcome of this fertilization of thought had enough African input to be regarded as an African progeny. Accordingly, practically all of them proffered their theories and prescriptions under the rubric of African socialism. No such labelling is possible in the work of African philosophers, but there are some patterns of preoccupation.

KWASI WIREDU

AFRICAN PHILOSOPHY, FRANCOPHONE

The imaginative and intellectual writings that have come out of French-speaking Africa have tended to be associated exclusively with the *négritude* movement and its global postulation of a black racial identity founded upon an original African essence. Beyond its polemical stance with regard to colonialism, the movement generated a theoretical discourse which served both as a means of self-validation for the African in particular and the black race in general. This discourse developed further as the elaboration of a new worldview derived from the African cultural inheritance of a new humanism that lays claim to universal significance.

Despite its prominence in the intellectual history of Francophone Africa and in the black world generally, *négritude* does not account for the full range of intellectual activity among the French-speaking African intelligentsia. The terms of its formulation have been challenged since its inception, leading to ongoing controversy. This challenge concerns the validity of the concept itself and its functional significance in contemporary African thought and collective life. It has involved a debate regarding the essential nature of the African, as well as the possibility of constructing a rigorous and coherent structure of ideas (with an indisputable philosophical status) derived from the belief systems and normative concepts implicit in the institutions and cultural practices subsisting from Africa's precolonial past.

The postcolonial situation has enlarged the terms of this debate in French-speaking Africa. It has come to cover a more diverse range of issues touching upon the African experience of modernity. As an extension of the 'indigenist' theme which is its point of departure, the cultural and philosophical arguments initiated by the adherents of *négritude* encompass a critical reappraisal of the Western tradition of philosophy and its historical consequences, as well as a consideration of its transforming potential in the African context. Beyond the essentialism implied by the concept of *négritude* and related theories of Africanism, the problem at the centre of French–African intellectual preoccupations relates to the modalities of African existence in the modern world.

From this perspective, the movement of ideas of the French-speaking African intelligentsia demonstrates the plurality of African discourse, as shaped by a continuing crisis of African consciousness provoked by the momentous process of transition to modernity. A convergence can be discerned between the themes and styles of philosophical discourse and inquiry in Francophone Africa and some of the significant currents of twentieth-century European philosophy and social thought engaged with the fundamental human issues raised by the impact of modern technological civilization.

Two dominant perspectives frame the evolution of contemporary thought and philosophical discourse in French-speaking Africa: the first is related to the question of identity and involves the reclamation of a cultural and spiritual heritage considered to be imperilled; the second relates to what has been called 'the dilemma of modernity' experienced as a problematic dimension of contemporary African life and consciousness.

AGNOSTICISM

In the popular sense, an agnostic is someone who neither believes nor disbelieves in God, whereas an atheist disbelieves in God. In the strict sense, however, agnosticism is the view that human reason is incapable of providing sufficient rational grounds to justify either the belief that God exists or the belief that God does not exist. In so far as one holds that our beliefs are rational only if they are sufficiently supported by human reason, the person who accepts the philosophical position of agnosticism will hold that neither the belief that God exists nor the belief that God does not exist is rational. In the modern period, agnostics have appealed largely to the philosophies of Hume and Kant as providing the justification for agnosticism as a philosophical position.

WILLIAM L. ROWE

AGRIPPA VON NETTESHEIM, HENRICUS CORNELIUS (1486–1535)

Famous in the sixteenth century for writings in which he steps forward variously as magician, occultist, evangelical humanist and philosopher, Agrippa shared with other humanist writers a thoroughgoing contempt for the philosophy of the scholastics. In his more evangelical moods Agrippa could be taken for a radical exponent of the *philosophia Christi* of his older contemporary Erasmus, or mistaken for a follower of Luther, whose early writings he actively disseminated in humanist circles. However, his deepest affinities are with magically inflected philosophies: the Neoplatonism and Hermetism of Marsilio Ficino, and the syncretic Christian Kabbalah of Giovanni Pico della Mirandola, Johannes Reuchlin and Johannes Trithemius.

As well as expounding an influential magical view of language, Agrippa contributed to the sixteenth-century revival of scepticism, denounced the 'tyranny' of those who obstructed a free search for truth, criticized the subjection of women and (with a courage unusual in his time) resisted and mocked the instigators of the witch-craze. Finding in Hermetic–Kabbalistic doctrines the inner truth both of religion and of philosophy, Agrippa was also aware of parallels between these magical doctrines and the Gnostic heresies. His heterodoxy made him a target for pious slanders: within several decades of his death he became the protagonist of demonological fictions which were soon absorbed into the legend of Dr Faustus.

MICHAEL H. KEEFER

AKRASIA

The Greek word '*akrasia*' is usually said to translate literally as 'lack of self-control', but it has come to be used as a general term for the phenomenon known as weakness of will, or incontinence, the disposition to act contrary to one's own considered judgment about what it is best to do. Since one variety of *akrasia* is the inability to act as one thinks right, *akrasia* is obviously important to the moral philosopher, but it is also frequently discussed in the context of philosophy of action. *Akrasia* is of interest to philosophers of action because although it seems clear that it does occur – that people often do act in ways which they believe to be contrary to their own best interests, moral principles or long-term goals – it also seems to follow from certain apparently plausible views about intentional action that *akrasia* is simply not possible. A famous version of the suggestion that genuine *akrasia* cannot exist is found in Socrates, as portrayed by Plato in the *Protagoras*. Socrates argues that it is impossible for a person's knowledge of what is best to be overcome by such things as the desire for pleasure – that one cannot choose a course of action which one knows full well to be less good than some alternative known to be available. Anyone who chooses to do something which is in fact worse than something they know they could have done instead, must, according to Socrates, have wrongly judged the relative values of the actions.

HELEN STEWARD

ALBERT THE GREAT (1200–80)

Albert the Great was the first scholastic interpreter of Aristotle's work in its entirety, as well as being a theologian and preacher. He left an encyclopedic body of work covering all areas of medieval knowledge, both in philosophy (logic, ethics, metaphysics, sciences of nature, meteorology, mineralogy, psychology, anthropology, physiology, biology, natural sciences and zoology) and in theology (biblical commentaries, systematic theology, liturgy and sermons). His philosophical work is based on both Arabic sources (including Alfarabi, Avicenna and Averroes) and Greek and Byzantine sources (such as Eustratius of Nicaea and Michael of Ephesus). Its aim was to insure that the Latin world was properly introduced to philosophy by providing a systematic exposition of Aristotelian positions.

Albert's method of exposition (paraphrase in the style of Avicenna rather than literal commentary in the style of Averroes), the relative heterogeneity of his sources and his own avowed general intention 'to list the opinions of the philosophers without asserting anything about the truth' of the opinions listed, all contribute to making his work seem eclectic or even theoretically inconsistent. This was compounded by the nature and number of spurious writings which, beginning in the fourteenth century, were traditionally attributed to him in the fields of alchemy, obstetrics, magic and necromancy, such as *The Great and the Little Albert*, *The Secrets of Women* and *The Secrets of the Egyptians*. This impression fades, however, when one examines the authentic works in the light of the history of medieval Aristotelianism and of the reception of the philosophical sources of late antiquity in the context of the thirteenth-century university.

ALCHEMY

Alchemy is the quest for an agent of material perfection, produced through a creative activity (*opus*), in which humans and nature collaborate. It exists in many cultures (China, India, Islam; in the Western world since Hellenistic times) under different specifications: aiming at the production of gold and/or other perfect substances from baser ones, or of the elixir that prolongs life, or even of life itself. Because of its purpose, the alchemists'

quest is always strictly linked to the religious doctrine of redemption current in each civilization where alchemy is practised.

In the Western world alchemy presented itself at its advent as a sacred art. But when, after a long detour via Byzantium and Islamic culture, it came back again to Europe in the twelfth century, adepts designated themselves philosophers. Since then alchemy has confronted natural philosophy for several centuries.

In contemporary thought the memory of alchemy was scarcely regarded, save as protochemistry or as a branch of esotericism, until interest in it was revived by C.G. Jung. Recent research is increasingly showing the complexity of alchemy and its multiple relation to Western thought.

ALIENATION

'Alienation' is a prominent term in twentieth-century social theory and social criticism, referring to any of various social or psychological evils which are characterized by a harmful separation, disruption or fragmentation which sunders things that properly belong together. People are alienated from one another when there is an interruption in their mutual affection or reciprocal understanding; they are alienated from political processes when they feel separated from them and powerless in relation to them. Reflection on your beliefs or values can also alienate you from them by undermining your attachment to them or your identification with them; they remain your beliefs or values *faute de mieux*, but are no longer yours in the way they should be. Alienation translates two distinct German terms: *Entfremdung* ('estrangement') and *Entäußerung* ('externalization'). Both terms originated in the philosophy of Hegel, specifically in his *Phenomenology of Spirit* (1807). Their influence, however, has come chiefly from their use by Karl Marx in his manuscripts of 1844 (first published in 1930). Marx's fundamental concern was with the alienation of wage labourers from their product, the grounds of which he sought in the alienated form of their labouring activity. In both Hegel and Marx, alienation refers fundamentally to a kind of activity in which the essence of the agent is posited as something external or alien, assuming the form of hostile domination over the agent.

ALLEN W. WOOD

ALIGHIERI, DANTE (1265–1321)

Although Dante never received a systematic training in philosophy, he tackled some of the most controversial philosophical problems of his time. In his theory of science, he asked how we are to explain the fact that science is a unified, strictly ordered system of knowledge. He answered by comparing the scientific disciplines with the celestial spheres, claiming that the system of knowledge mirrors the cosmological order. In his political philosophy, he asked why all humans want to live in a peaceful society. All humans seek full use of their cognitive capacity, was his answer, and they can achieve it only if they interact socially. In his philosophy of nature, Dante asked what brings about the order of the elements, and suggested that the elements obey the laws of a universal nature in a strictly ordered cosmos. He elaborated all his answers in a scholastic framework that made use of both Aristotelian and Neoplatonic traditions.

ALTERITY AND IDENTITY, POSTMODERN THEORIES OF

Theories of alterity and identity can be said to be 'postmodern' if they challenge at least two key features of modern philosophy: (1) the Cartesian attempt to secure the legitimacy of knowledge on the basis of a subject that immediately knows itself and (2) the Hegelian attempt to secure self-knowledge and self-recognition by showing that knowledge and recognition are mediated by the whole. Postmodern thought does not necessarily champion a wholly other, but it generally conceives of self-identity in terms of a radical alterity.

See also: POSTMODERNISM

PETER FENVES

ALTHUSSER, LOUIS PIERRE (1918–90)

Louis Althusser was the most influential philosopher to emerge in the revival of Marxist theory occasioned by the radical movements of the 1960s. His influence is, on the face of it, surprising, since Althusser's Marx is not the theorist of revolutionary self-emancipation celebrated by the early Lukács. According to Althusser, Marx, along with Freud, was responsible for a 'decentring' of the human subject. History is 'a process without a subject'. Its movement is beyond the comprehension of individual or collective subjects, and can only be grasped by a scientific 'theoretical practice' which keeps its distance from everyday experience. This austere version of Marxism nevertheless

captured the imagination of many young intellectuals by calling for a 'return to Marx', with the implication that his writings had been distorted by the official communist movement. In fact, Althusser later conceded, his was an 'imaginary Marxism', a reconstruction of historical materialism reflecting the same philosophical climate that produced the post-structuralist appropriations of Nietzsche and Heidegger by Deleuze, Derrida and Foucault. Most of the philosophical difficulties in which Althusser found himself can be traced back to the impossibility of fusing Marx's and Nietzsche's thought into a new synthesis.

ALTRUISM

See Egoism and altruism

AMBIGUITY

A word, phrase or sentence is ambiguous if it has more than one meaning. The word 'light', for example, can mean not very heavy or not very dark. Words like 'light', 'note', 'bear' and 'over' are *lexically* ambiguous. They induce ambiguity in phrases or sentences in which they occur, such as 'light suit' and 'The duchess can't bear children'. However, phrases and sentences can be ambiguous even if none of their constituents is. The phrase 'porcelain egg container' is *structurally* ambiguous, as is the sentence 'The police shot the rioters with guns'. Ambiguity can have both a lexical and a structural basis, as with sentences like 'I left her behind for you' and 'He saw her duck'.

The notion of ambiguity has philosophical applications. For example, identifying an ambiguity can aid in solving a philosophical problem. Suppose one wonders how two people can have the same idea, say of a unicorn. This can seem puzzling until one distinguishes 'idea' in the sense of a particular psychological occurrence, a mental representation, from 'idea' in the sense of an abstract, shareable concept. On the other hand, gratuitous claims of ambiguity can make for overly simple solutions. Accordingly, the question arises of how genuine ambiguities can be distinguished from spurious ones. Part of the answer consists in identifying phenomena with which ambiguity may be confused, such as vagueness, unclarity, inexplicitness and indexicality.

ANALYSIS, PHILOSOPHICAL ISSUES IN

The term 'mathematical analysis' refers to the major branch of mathematics which is concerned with the theory of functions and includes the differential and integral calculus. Analysis and the calculus began as the study of curves, calculus being concerned with tangents to and areas under curves. The focus was shifted to functions following the insight, due to Leibniz and Isaac Newton in the second half of the seventeenth century, that a curve is the graph of a function. Algebraic foundations were proposed by Lagrange in the late eighteenth century; assuming that any function always took an expansion in a power series, he defined the derivatives from the coefficients of the terms. In the 1820s his assumption was refuted by Cauchy, who had already launched a fourth approach, like Newton's based on limits, but formulated much more carefully. It was refined further by Weierstrass, by means which helped to create set theory. Analysis also encompasses the theory of limits and of the convergence and divergence of infinite series; modern versions also use point set topology. It has taken various forms over the centuries, of which the older ones are still represented in some notations and terms. Philosophical issues include the status of infinitesimals, the place of logic in the articulation of proofs, types of definition, and the (non-)relationship to analytic proof methods.

See also: Continuum hypothesis

I. GRATTAN-GUINNESS

ANALYTICAL PHILOSOPHY

Philosophical analysis is a method of inquiry in which one seeks to assess complex systems of thought by 'analysing' them into simpler elements whose relationships are thereby brought into focus. This method has a long history, but became especially prominent at the start of the twentieth century and, by becoming integrated into Russell's development of logical theory, acquired a greater degree of sophistication than before. The logical positivists developed the method further during the 1930s and, in the context of their anti-metaphysical programme, held that analysis was the only legitimate philosophical inquiry. Thus for them philosophy could only be 'analytical philosophy'.

After 1945 those philosophers who wanted to expand philosophical inquiries beyond the limits prescribed by the positivists extended the understanding of analysis to include accounts of the general structures of language and thought without the earlier commitment to the identification of

'simple' elements of thought. Hence there developed a more relaxed conception of 'linguistic analysis' and the understanding of 'analytical philosophy' was modified in such a way that a critical concern with language and meaning was taken to be central to it, leading, indeed, to a retrospective re-evaluation of the role of Frege as a founder of analytical philosophy. At the same time, however, Quine propounded influential arguments which suggest that methods of analysis can have no deep significance because there is no determinate structure to systems of thought or language for the analytical philosopher to analyse and assess. Hence some contemporary philosophers proclaim that we have now reached 'the end of analytical philosophy'. But others, who find Quine's arguments unpersuasive, hold that analytical philosophy has virtues quite sufficient to ensure it a role as a central philosophical method for the foreseeable future.

See also: Logical positivism

THOMAS BALDWIN

ANALYTICITY

In *Critique of Pure Reason* Kant introduced the term 'analytic' for judgments whose truth is guaranteed by a certain relation of 'containment' between the constituent concepts, and 'synthetic' for judgments which are not like this. Closely related terms were found in earlier writings of Locke, Hume and Leibniz. In Kant's definition, an analytic judgment is one in which 'the predicate B belongs to the subject A, as something which is (covertly) contained in this concept A' (*Critique* 1781/1787). Kant called such judgments 'explicative', contrasting them with synthetic judgments which are 'ampliative'. A paradigmatic analyticity would be: bachelors are unmarried. Kant assumed that knowledge of analytic necessities has a uniquely transparent sort of explanation. In the succeeding two centuries the terms 'analytic' and 'synthetic' have been used in a variety of closely related but not strictly equivalent ways. In the early 1950s Morton White and W.V. Quine argued that the terms were fundamentally unclear and should be eschewed. Although a number of prominent philosophers have rejected their arguments, there prevails a scepticism about 'analytic' and the idea that there is an associated category of necessary truths having privileged epistemic status.

GEORGE BEALER

ANAPHORA

Anaphora describes a dependence of the interpretation of one natural language expression on the interpretation of another natural language expression. For example, the pronoun 'her' in (1) below is anaphorically dependent for its interpretation on the interpretation of the noun phrase 'Sally' because 'her' refers to the same person 'Sally' refers to.

(1) Sally likes her car.

As (2) below illustrates, anaphoric dependencies also occur across sentences, making anaphora a 'discourse phenomenon':

(2) A farmer owned a donkey. He beat it.

The analysis of anaphoric dependence has been the focus of a great deal of study in linguistics and philosophy. Anaphoric dependencies are difficult to accommodate within the traditional conception of compositional semantics of Tarski and Montague precisely because the meaning of anaphoric elements is dependent on other elements of the discourse.

Many expressions can be used anaphorically. For instance, anaphoric dependencies hold between the expression 'one' and the indefinite noun phrase 'a labrador' in (3) below; between the verb phrase 'loves his mother' and a 'null' anaphor (or verbal auxiliary) in (4); between the prepositional phrase 'to Paris' and the lexical item 'there' in (5); and between a segment of text and the pronoun 'it' in (6).

(3) Susan has a labrador. I want one too.

(4) John loves his mother. Fred does too.

(5) I didn't go to Paris last year. I don't go there very often.

(6) One plaintiff was passed over for promotion. Another didn't get a pay increase for five years. A third received a lower wage than men doing the same work. But the jury didn't believe any of it.

Some philosophers and linguists have also argued that verb tenses generate anaphoric dependencies.

NICHOLAS ASHER

ANARCHISM

Anarchism is the view that a society without the state, or government, is both possible and desirable. Although there have been intimations of the anarchist outlook throughout history, anarchist ideas emerged in their modern form in the late eighteenth and early nineteenth centuries in the wake of the French and Industrial Revolutions.

All anarchists support some version of each of the following broad claims: (1) people have no general

obligation to obey the commands of the state; (2) the state ought to be abolished; (3) some kind of stateless society is possible and desirable; (4) the transition from state to anarchy is a realistic prospect

Within this broad framework there is a rich variety of anarchist thought. The main political division is between the 'classical' or socialist school, which tends to reject or restrict private property, and the 'individualist' or libertarian tradition, which defends private acquisition and looks to free market exchange as a model for the desirable society. Philosophical differences follow this division to some extent, the classical school appealing principally to natural law and perfectionist ethics, and the individualists to natural rights and egoism. Another possible distinction is between the 'old' anarchism of the nineteenth century (including both the classical and individualist traditions) and the 'new' anarchist thought that has developed since the Second World War, which applies the insights of such recent ethical currents as feminism, ecology and postmodernism.

Anarchists have produced powerful arguments denying any general obligation to obey the state and pointing out the ill effects of state power. More open to question are their claims that states ought to be abolished, that social order is possible without the state and that a transition to anarchy is a realistic possibility.

GEORGE CROWDER

ANAXIMANDER (610–after 546 BC)

The Greek philosopher Anaximander of Miletus followed Thales in his philosophical and scientific interests. He wrote a book, of which one fragment survives, and is the first Presocratic philosopher about whom we have enough information to reconstruct his theories in any detail. He was principally concerned with the origin, structure and workings of the world, and attempted to account for them consistently, through a small number of principles and mechanisms. Like other thinkers of his tradition, he gave the Olympian gods no role in creating the world or controlling events. Instead, he held that the world originated from a vast, eternal, moving material of no definite nature, which he called *apeiron* ('boundless' or 'unlimited'). From this, through obscure processes including one called 'separation off', arose the world as we know it. Anaximander described the *kosmos* (world) and stated the distances of the celestial bodies from the earth. He accounted for the origin of animal life and explained how humans first emerged. He pictured the world as a battleground in which opposite natures, such as hot and cold, constantly encroach upon one another, and described this process as taking place with order and regularity.

RICHARD MCKIRAHAN

ANAXIMENES (6th century BC)

The Greek philosopher Anaximenes of Miletus followed Anaximander in his philosophical and scientific interests. Only a few words survive from his book, but there is enough other information to give us a picture of his most important theories. Like the other early Presocratic philosophers he was interested in the origin, structure and composition of the universe, as well as the principles on which it operates. Anaximenes held that the primary substance – both the source of everything else and the material out of which it is made – is air. When rarefied and condensed it becomes other materials, such as fire, water and earth. The primordial air is infinite in extent and without beginning or end. It is in motion and divine. Air generated the universe through its motion, and continues to govern it. The human soul is composed of air and it is likely that Anaximenes believed the entire *kosmos* (world) to be alive, with air functioning as its soul. Like other Presocratics, he proposed theories of the nature of the heavenly bodies and their motions, and of meteorological and other natural phenomena.

ANCIENT PHILOSOPHY

Introduction

The philosophy of the Greco-Roman world from the sixth century BC to the sixth century AD laid the foundations for all subsequent Western philosophy. Its greatest figures are Socrates (fifth century BC) and Plato and Aristotle (fourth century BC). But the enormously diverse range of further important thinkers who populated the period includes the Presocratics and Sophists of the sixth and fifth centuries BC; the Stoics, Epicureans and sceptics of the Hellenistic age; and the many Aristotelian and (especially) Platonist philosophers who wrote under the Roman Empire, including the great Neoplatonist Plotinus. Ancient philosophy was principally pagan, and was finally eclipsed by Christianity in the sixth century AD, but it was so comprehensively annexed by its conqueror that it came, through Christianity, to dominate medieval and Renaissance

philosophy. This eventual symbiosis between ancient philosophy and Christianity may reflect the fact that philosophical creeds in late antiquity fulfilled much the same role as religious movements, with which they shared many of their aims and practices.

Only a small fraction of ancient philosophical writings have come down to us intact. The remainder can be recovered, to a greater or lesser extent, by piecing together fragmentary evidence from sources which refer to them.

1 Main features

'Ancient' philosophy is that of classical antiquity, which not only inaugurated the entire European philosophical tradition but has exercised an unparalleled influence on its style and content. It is conventionally considered to start with THALES in the mid-sixth century BC, although the Greeks themselves frequently made Homer (*c*.700 BC) its true originator. Officially it is often regarded as ending in 529 AD, when the Christian emperor Justinian is believed to have banned the teaching of pagan philosophy at Athens. However, this was no abrupt termination, and the work of Platonist philosophers continued for some time in self-imposed exile (see NEOPLATONISM).

Down to and including Plato (in the first half of the fourth century BC), philosophy did not develop a significant technical terminology of its own – unlike such contemporary disciplines as mathematics and medicine. It was Plato's pupil Aristotle, and after him the Stoics (see STOICISM), who made truly decisive contributions to the philosophical vocabulary of the ancient world.

Ancient philosophy was above all a product of Greece and the Greek-speaking parts of the Mediterranean, which came to include southern Italy, Sicily, western Asia and large parts of North Africa, notably Egypt. From the first century BC, a number of Romans became actively engaged in one or other of the Greek philosophical systems, and some of them wrote their own works in Latin (see LUCRETIUS; CICERO). But Greek remained the *lingua franca* of philosophy. Although much modern philosophical terminology derives from Latinized versions of Greek technical concepts, most of these stem from the Latin vocabulary of medieval Aristotelianism, not directly from ancient Roman philosophical writers.

2 The sixth and fifth centuries BC

The first phase, occupying most of the sixth and fifth centuries BC, is generally known as PRESOCRATIC PHILOSOPHY. Its earliest practitioners (THALES; ANAXIMANDER; ANAXIMENES) came from Miletus, on the west coast of modern Turkey. The dominant concern of the Presocratic thinkers was to explain the origin and regularities of the physical world and the place of the human soul within it (see especially PYTHAGOREANISM; HERACLITUS; EMPEDOCLES; DEMOCRITUS), although the period also produced such rebels as the Eleatic philosophers (PARMENIDES; ZENO OF ELEA), whose radical monism sought to undermine the very basis of cosmology by reliance on a priori reasoning.

The label 'Presocratic' acknowledges the traditional view that SOCRATES (469–399 BC) was the first philosopher to shift the focus away from the natural world to human values. In fact, however, this shift to a large extent coincides with the concerns of his contemporaries the Sophists, who professed to teach the fundamentals of political and social success and consequently were also much concerned with moral issues (see SOPHISTS). But the persona of Socrates became, and has remained ever since, so powerful an icon for the life of moral scrutiny that it is his name that is used to mark this watershed in the history of philosophy. In the century or so following his death, many schools looked back to him as the living embodiment of philosophy and sought the principles of his life and thought in philosophical theory.

3 The fourth century BC

Socrates and the Sophists helped to make Athens the philosophical centre of the Greek world, and it was there, in the fourth century, that the two greatest philosophers of antiquity lived and taught, namely Plato and Aristotle. PLATO, Socrates' pupil, set up his school the Academy in Athens. Plato's published dialogues are literary masterpieces as well as philosophical classics, and develop, albeit unsystematically, a global philosophy which embraces ethics, politics, physics, metaphysics (see FORMS, PLATONIC), epistemology (see INNATENESS IN ANCIENT PHILOSOPHY), aesthetics and psychology.

The Academy's most eminent alumnus was ARISTOTLE, whose own school the Lyceum came for a time to rival the Academy's importance as an educational centre. Aristotle's highly technical but also often provisional and exploratory school

treatises may not have been intended for publication; at all events, they did not become widely disseminated and discussed until the late first century BC. The main philosophical treatises (leaving aside his important zoological works) include seminal studies in all the areas covered by Plato, plus logic, a branch of philosophy pioneered by Aristotle. These treatises are, like Plato's, among the leading classics of Western philosophy.

Platonism and Aristotelianism were to become the dominant philosophies of the Western tradition from the second century AD at least until the end of the Renaissance, and the legacy of both remains central to Western philosophy today.

4 Hellenistic philosophy

Down to the late fourth century BC, philosophy was widely seen as a search for universal understanding, so that in the major schools its activities could comfortably include, for example, biological and historical research. In the ensuing era of Hellenistic philosophy, however, a geographical split helped to demarcate philosophy more sharply as a self-contained discipline. Alexandria, with its magnificent library and royal patronage, became the new centre of scientific, literary and historical research, while the philosophical schools at Athens concentrated on those areas which correspond more closely to philosophy as it has since come to be understood. The following features were to characterize philosophy not only in the Hellenistic age but also for the remainder of antiquity.

The three main parts of philosophy were most commonly labelled 'physics' (a primarily speculative discipline, concerned with such concepts as causation, change, god and matter, and virtually devoid of empirical research), 'logic' (which sometimes included epistemology) and 'ethics'. Ethics was agreed to be the ultimate focus of philosophy, which was thus in essence a systematized route to personal virtue (see ARETĒ) and happiness (see EUDAIMONIA). There was also a strong spiritual dimension. One's religious beliefs – that is, the way one rationalized and elaborated one's own (normally pagan) beliefs and practices concerning the divine – were themselves an integral part of both physics and ethics, never a mere adjunct of philosophy.

The dominant philosophical creeds of the Hellenistic age (officially 323–31 BC) were Stoicism (founded by ZENO OF CITIUM) and Epicureanism (founded by Epicurus) (see STOICISM; EPICUREANISM). Scepticism was also a powerful force, largely through the Academy (see CARNEADES), which in this period functioned as a critical rather than a doctrinal school, and also, starting from the last decades of the era, through Pyrrhonism

5 The imperial era

The crucial watershed belongs, however, not at the very end of the Hellenistic age (31 BC, when the Roman empire officially begins), but half a century earlier in the 80s BC. Political and military upheavals at Athens drove most of the philosophers out of the city, to cultural havens such as Alexandria and Rome. The philosophical institutions of Athens never fully recovered, so that this decentralization amounted to a permanent redrawing of the philosophical map. (The chairs of Platonism, Aristotelianism, Stoicism and Epicureanism which the philosopher-emperor Marcus Aurelius established at Athens in AD 176 were a significant gesture, but did not fully restore Athens' former philosophical pre-eminence.) Philosophy was no longer, for most of its adherents, a living activity within the Athenian school founded by Plato, Aristotle, Zeno or Epicurus. Instead it was a subject pursued in small study groups led by professional teachers all over the Greco-Roman world. To a large extent, it was felt that the history of philosophy had now come to an end, and that the goal now was to seek the correct interpretation of the 'ancients' by close study of their texts. One symptom of this feeling is that doxography – the systematic cataloguing of philosophical and scientific opinions – concentrated largely on the period down to about 80 BC, as did the biographical history of philosophy written *c.* AD 300 by DIOGENES LAERTIUS.

Another such symptom is that a huge part of the philosophical activity of late antiquity went into the composition of commentaries on classic philosophical texts. In this final phase of ancient philosophy, conveniently called 'imperial' because it more or less coincides with the era of the Roman empire, the Hellenistic creeds were gradually eclipsed by the revival of doctrinal Platonism, based on the close study of Plato's texts, out of which it developed a massively elaborate metaphysical scheme. Aristotle was usually regarded as an ally by these Platonists, and became therefore himself the focus of many commentaries (see NEOPLATONISM). Despite its formal concern with recovering the wisdom of the ancients, however, this age produced many powerfully original thinkers, of whom the greatest is PLOTINUS.

6 Schools and movements

The early Pythagoreans constituted the first philosophical group that can be called even approximately a 'school'. They acquired a reputation for secrecy, as well as for virtually religious devotion to the word of their founder PYTHAGORAS. 'He himself said it' (best known in its Latin form '*ipse*

dixit') was alleged to be their watchword. In some ways it is more accurate to consider them a sect than a school, and their beliefs and practices were certainly intimately bound up in religious teachings about the soul's purification.

It is no longer accepted, as it long was, that the Athenian philosophical schools had the status of formal religious institutions for the worship of the muses. Their legal and institutional standing is in fact quite obscure. Both the Academy and the Lyceum were so named after public groves just outside the walls of Athens, in which their public activities were held. The Stoics too got their name from the public portico, or 'stoa', in which they met, alongside the Athenian agora. Although these schools undoubtedly also conducted classes and discussions on private premises too, it was their public profile that was crucial to their identity as schools. In the last four centuries BC, prospective philosophy students flocked to Athens from all over the Greek world, and the high public visibility of the schools there was undoubtedly cultivated partly with an eye to recruitment. Only the Epicurean school kept its activities out of the public gaze, in line with Epicurus' policy of minimal civic involvement.

A school normally started as an informal grouping of philosophers with a shared set of interests and commitments, under the nominal leadership of some individual, but without a strong party line to which all members owed unquestioning allegiance. In the first generation of the Academy, for example, many of Plato's own leading colleagues dissented from his views on central issues. The same openness is discernible in the first generations of the other schools, even (if to a much lesser extent) that of the Epicureans. However, after the death of the founder the picture usually changed. His word thereafter became largely beyond challenge, and further progress was presented as the supplementation or reinterpretation of the founder's pronouncements, rather than as their replacement.

To this extent, the allegiance which in the long term bound a school together usually depended on a virtually religious reverence for the movement's foundational texts, which provided the framework within which its discussions were conducted. The resemblance to the structure of religious sects is no accident. In later antiquity, philosophical and religious movements constituted in effect a single cultural phenomenon, and competed for the same spiritual and intellectual high ground. This includes Christianity, which became a serious rival to pagan philosophy (primarily Platonism) from the third century onwards, and eventually triumphed over it. In seeking to understand such spiritual movements of late antiquity as HERMETISM, GNOSTICISM, Neo-Pythagoreanism, Cynicism and even NEOPLATONISM itself, and their concern with such values as asceticism, self-purificaton and self-divinization, it is inappropriate to insist on a sharp division between philosophy and religion.

'Ancient philosophy' is traditionally understood as pagan and is distinguished from the Christian Patristic philosophy of late antiquity (see PATRISTIC PHILOSOPHY). But it was possible to put pagan philosophy at the service of Judaism (see PHILO OF ALEXANDRIA) or Christianity (see for example ORIGEN; AUGUSTINE; BOETHIUS; PHILOPONUS), and it was indeed largely in this latter capacity that the major systems of ancient philosophy eventually became incorporated into MEDIEVAL PHILOSOPHY and RENAISSANCE PHILOSOPHY, which they proceeded to dominate.

This extensive overlap between philosophy and religion also reflects to some extent the pervasive influence of philosophy on the entire culture of the ancient world. Rarely regarded as a detached academic discipline, philosophy frequently carried high political prestige, and its modes of discourse came to infect disciplines as diverse as medicine, rhetoric, astrology, history, grammar and law. The work of two of the greatest scientists of the ancient world, the doctor Galen and the astronomer Ptolemy, was deeply indebted to their respective philosophical backgrounds.

7 Survival

A very substantial body of works by ancient philosophical writers has survived in manuscript. These are somewhat weighted towards those philosophers – above all Plato, Aristotle and the Neoplatonists – who were of most immediate interest to the Christian culture which preserved them throughout the Middle Ages, mainly in the monasteries, where manuscripts were assiduously copied and stored. Some further ancient philosophical writings have been recovered through translations into Arabic and other languages, or on excavated scraps of papyrus. The task of reconstituting the original texts of these works has been a major preoccupation of modern scholarship.

For the vast majority of ancient philosophers, however, our knowledge of them depends on secondary reports of their words and ideas in other writers, of whom some are genuinely interested in recording the history of philosophy, but others bent on discrediting the views they attribute to them. In such cases of secondary attestation, strictly a 'fragment' is a verbatim quotation, while indirect reports are called 'testimonia'. However, this distinction is not always rigidly maintained, and indeed the sources on which we rely rarely operate

with any explicit distinction between quotation and paraphrase.

It is a tribute to the philosophical genius of the ancient world that, despite the suppression and distortion which its contributions have suffered over two millennia, they remain central to any modern conspectus of what philosophy is and can be.

ANIMAL LANGUAGE AND THOUGHT

The question of animal language and thought has been debated since ancient times. Some have held that humans are exceptional in these respects, others that humans and animals are continuous with respect to language and thought. The issue is important because our self-image as a species is at stake.

Arguments for human exceptionalism can be classified as Cartesian, Wittgensteinian and behaviourist. What these arguments have in common is the view that language and thought are closely associated, and animals do not have language. The ape language experiments of the 1960s and 1970s were especially important against this background: if apes could learn language then even the advocates of human exceptionalism would have to admit that they have thoughts. It is now generally believed that whatever linguistic abilities apes have shown have been quite rudimentary. Yet many sceptics are willing to grant that in some cases apes did develop linguistic skills to some extent, and clearly evidenced thought. Studies of other animals in captivity and various animals in the wild have provided evidence of highly sophisticated communicative behaviour. Cognitive ethology and comparative psychology have emerged as the fields that study animal thought. While there are conceptual difficulties in grounding these fields, it appears plausible that many animals have thoughts and these can be scientifically investigated.

DALE JAMIESON

ANIMALS AND ETHICS

Introduction

Does morality require that we respect the lives and interests of nonhuman animals? The traditional doctrine was that animals were made for human use, and so we may dispose of them as we please. It has been argued, however, that this is a mere ‘speciesist’ prejudice and that animals should be given more or less the same moral consideration as humans. If this is right, we may be morally required to be vegetarians; and it may turn out that laboratory research using animals, and many other such practices, are more problematic than, previously has been realized.

1 The traditional view

In some Eastern systems of thought, animals are accorded great respect. The Jains of India hold that all life is sacred, drawing no sharp distinction between human and nonhuman life. They are therefore vegetarians, as are Buddhists, whose sacred writings forbid all needless killing. In the West, however, it was traditionally believed that animals were made for human use. This idea, familiar from the Old Testament book of Genesis and elaborated by a long line of Jewish and Christian thinkers, also formed part of Aristotle’s worldview. Aristotle taught that ‘nature does everything for a purpose’, and so, just as plants exist to provide food for animals, animals exist to provide food and other ‘aids in life’ for humans.

This was cosmology with a moral point. Aquinas, who emphasized that it was God himself who provided the animals for human use, made the point explicit: ‘Therefore,’ he said, ‘it is not wrong for man to make use of them, by killing or in any other way whatever’ (*Summa contra gentiles*). Are there, then, no limits on how animals may be treated? One might think we have a duty to be kind to them out of simple charity. But Aquinas insisted that this is not so. ‘Charity,’ he said, ‘does not extend to irrational creatures.’

There was, however, one way in which animals could gain a degree of protection. They might be the incidental beneficiaries of obligations owed to humans. If someone has promised to look after your dog, she is obliged to care for it. But the obligation is owed to you, not to the dog. There might even be a general duty not to torment animals, because, as KANT put it, 'He who is cruel to animals becomes hard also in his dealings with men' (*Lectures on Ethics* 1780–1). But once again, the point was to protect the men, not the animals. (This has sometimes been called the 'indirect duty view' – that we can have duties to animals, but only indirect ones.)

This view might seem extreme in its near total disregard for nonhumans. Nevertheless, the idea that animals are essentially resources for human use was accepted by almost every important thinker in the Western tradition – including such figures as St Francis, who is popularly but wrongly believed to have advocated a more charitable stance. For this view to be defensible, however, there must be some difference between humans and other animals that would explain why humans have a privileged moral status. Traditional thought cited two such differences. For Aristotle, the difference was that humans alone are rational. Religious figures added that man alone was made in the image of God. These explanations seemed sufficient until 1859, when Darwin's *On the Origin of Species* (1859) transformed our understanding of man's relation to the rest of nature (see DARWIN, C.R.).

2 Challenges to the traditional view

Darwin demonstrated that humans are not 'set apart' from other animals, but are related to them by evolutionary descent (see EVOLUTION, THEORY OF). It is no accident that we bear such a startling resemblance to the apes. Our bones and muscles are but modified versions of the ape's bones and muscles – they are similar because we inherited them from the same ancestors. The same is true of our rational faculties. Man is not *the* rational animal, for other animals also possess a degree of rationality. How could it be otherwise, when our brains developed from a common source? Darwin went so far as to declare, 'There is no fundamental difference between man and the higher mammals in their mental faculties' (*Origin of the Species*). Such differences as do exist, he said, are matters of degree, not kind.

Today it is widely accepted that Darwin was right, at least in the main outlines of his view, and this poses an obvious ethical dilemma: if humans are similar in so many ways to other animals, and humans merit moral protection, then why should other animals not merit protection too? As Asa Gray, Darwin's friend in America, put it, 'Human beings may be more humane when they realize that, as their dependent associates live a life in which man has a share, so they have rights which man is bound to respect' (*Natural Science and Religion* 1880). Darwin himself regarded cruelty to animals, along with slavery, as one of the two great human moral failings.

Another nineteenth-century development also cast doubt on the traditional exclusion of animals from the range of moral concern. The utilitarians, led by Jeremy Bentham and John Stuart Mill, argued that morality is fundamentally a matter of seeking to promote happiness and prevent suffering (see UTILITARIANISM). But Bentham saw no reason to limit moral concern to human suffering. In fact, in *An Introduction to the Principles of Morals and Legislation* he suggested that disregard for animals was a form of discrimination analogous to racism:

> The day may come when the rest of the animal creation may acquire the rights which never could have been withholden from them but by the hand of tyranny. The French have already discovered that the blackness of the skin is no reason why a human being should be abandoned without redress to the caprice of a tormentor. It may one day come to be recognized that the number of the legs, the villosity of the skin, or the termination of the os *sacrum* are reasons equally insufficient for abandoning a sensitive being to the same fate . . . . The question is not, Can they *reason*? nor, Can they *talk*? but, Can they *suffer*?
> (1789; original emphasis)

It must be noted, however, that for most of Western history the moral status of animals did not seem to be much of an issue, and philosophers did not write very extensively about it (Bentham's discussion, for example, is confined to a footnote). The subject began to be widely discussed among philosophers only after the publication of Peter Singer's *Animal Liberation* in 1975.

3 The contemporary debate

One of the striking things about the debate concerning animals is that it is possible to reach radical ethical conclusions by invoking only the most common moral principles. The idea that it is wrong to cause suffering, unless there is a sufficient justification, is one of the most basic moral principles, shared by virtually everyone. Yet the consistent application of this principle seems to lead straight to vegetarianism or at least to the avoidance of factory-farmed meat. The argument is disarmingly simple. In modern factory farms, animals

who are raised and slaughtered for food suffer considerable pain. Since we could easily nourish ourselves without eating them, our only reason for eating them seems to be our enjoyment of how they taste. So, unless one thinks our gustatory pleasure is a sufficient justification for causing torment, the obvious conclusion is that we are wrong to produce and consume such products.

Other arguments appeal to less commonplace notions. The word 'speciesism' was coined by Richard Ryder, a British psychologist who ceased experimenting on animals after becoming convinced it was immoral, and was popularized by Singer in *Animal Liberation*. Speciesism is said to be analogous to racism. Just as racists unjustifiably give greater weight to the interests of the members of their own race, speciesists unjustifiably give greater weight to the interests of the members of their own species (see DISCRIMINATION).

Consider, for example, the very different standards we have for using humans and nonhumans in laboratory research. Why do we think it permissible to perform a painful and destructive experiment on, say, a rhesus monkey, when we would not perform the same experiment on a human? Someone might suggest that, say, humans are more intelligent than monkeys, or that their social relationships are more complex. But consider mentally retarded persons whose cognitive and social capacities are no greater than those of the animal. Would it be permissible to perform the same experiment on them? Many people think that, simply because they are human, it would not. This is speciesism laid bare: there is no difference between the human and the nonhuman in their abilities to think, feel or suffer, and yet the human's welfare counts for more.

This line of thought suggests that animals may be treated differently from humans when, and only when, there are morally relevant differences between them. It may be permissible to admit humans, but not other animals, to universities, because humans can read and other animals cannot. But in cases where there are no relevant differences, they must be treated alike. This is the sense in which humans and nonhumans can be said to be morally 'equal': the bare fact that one is human never itself counts for anything, just as the bare fact that one has one skin colour or another never itself counts for anything. So we may not treat an animal in any way in which we would not be willing to treat a human with the same intellectual and emotional capacities.

Such arguments have, of course, provoked lively opposition. Many philosophers find it difficult to believe that mere animals could have such powerful claims on us. Morality, they say, is fundamentally a human institution established to protect human rights and human interests (see MORALITY AND ETHICS). Contractarianism, which has emerged in the latter half of the twentieth century as the principal rival to utilitarianism, makes this point most clearly. According to this view, morality rests on agreements of mutual benefit. Morality arises within a community when each person agrees to 'play the social game', respecting other people's rights and interests, provided others will do so as well. This agreement makes social living possible, and everyone benefits from it. But animals are unable to participate in such agreements, so they do not come within the sphere of moral protection.

In addition to initiating a philosophical debate, Peter Singer's book is perhaps the most conspicuous example of a philosophical work triggering a social movement. The animal rights movement, with its principled opposition to such practices as factory farming, the use of animals in commercial and scientific research, and the fur trade, has become a familiar part of contemporary life. Rarely, if ever, have philosophical thinking and social activism been linked so closely.

JAMES RACHELS

ANOMALOUS MONISM

Anomalous monism, proposed by Donald Davidson in 1970, implies that all events are of one fundamental kind, namely physical. But it does not deny that there are mental events; rather, it implies that every mental event is some physical event or other. The idea is that someone's thinking at a certain time that the earth is round, for example, might be a certain pattern of neural firing in their brain at that time, an event which is both a thinking that the earth is round (a type of mental event) and a pattern of neural firing (a type of physical event). There is just one event, that can be characterized both in mental terms and in physical terms. If mental events are physical events, they can, like all physical events, be explained and predicted (at least in principle) on the basis of laws of nature cited in physical science. However, according to anomalous monism, events cannot be so explained or predicted as described in mental terms (such as thinking, desiring, itching and so on), but only as described in physical terms. The

distinctive feature of anomalous monism as a brand of physical monism is that it implies that mental events as such (that is, as described in mental terms) are anomalous – they cannot be explained or predicted on the basis of strict scientific laws.

BRIAN P. MCLAUGHLIN

ANSCOMBE, GERTRUDE ELIZABETH MARGARET (1919–2001)

Elizabeth Anscombe has contributed to all principal areas of philosophy, most influentially to ethics and the philosophy of mind. She is the founder of contemporary action theory, and an important source of the revival of interest in virtue ethics. The chief influences on her thought are the work of her teacher, Ludwig Wittgenstein, much of which she has translated and of which she is an important interpreter, and the classical and medieval traditions, as found in Aristotle and Aquinas. She has also made a number of contributions to the defence of Roman Catholic religious belief.

MICHAEL THOMPSON

ANSELM OF CANTERBURY (1033–1109)

Anselm of Canterbury, also known as Anselm of Aosta and Anselm of Bec or Saint Anselm, was first a student, then a monk, later prior and finally abbot of the monastery of Bec in Normandy, before being elected Archbishop of Canterbury in 1093. He remains one of the best-known and most readily engaging philosophers and theologians of medieval Europe. His literary corpus consists of eleven treatises or dialogues, the most important of which are the philosophical works *Monologion* and *Proslogion* and the magnificent theological work *Cur deus homo* (Why God Became a [God-]Man). He also left three meditations, nineteen prayers, 374 extant letters including *Epistolae de Sacramentis* (Letters on the Sacraments) and a collection of philosophical fragments, together with a compilation of his sayings (*Dicta Anselmi*) by Alexander, a monk of Canterbury, and a compilation of his reflections on virtue, *De morum qualitate per exemplorum coaptationem* (On Virtues and Vices as Illustrated by a Collage of Examples), possibly also by a monk at Canterbury.

At Bec Anselm wrote his first philosophical treatise, the *Monologion*, a title signifying a soliloquy. This work was followed by the *Proslogion*, the title meaning an address (of the soul to God). At Bec he also completed the philosophical dialogues *De grammatico* (On (an) Expert in Grammar), *De veritate* (On Truth), *De libertate arbitrii* (Freedom of Choice) and *De casu diaboli* (The Fall of the Devil). Near the end of his time at Bec, he turned his attention to themes more theological, drafting a first version of *De incarnatione Verbi* (The Incarnation of the Word) before September 1092 and completing the final revision around the beginning of 1094. During his time in office at Canterbury, which included two long exiles from England (1097–1100 and 1103–6), he wrote the *Cur deus homo*, followed by the concisely reasoned treatises *De conceptu virginali et originali peccati* (The Virgin Conception and Original Sin), *De processione Spiritus Sancti* (The Procession of the Holy Spirit) and *De concordia praescientiae et praedestinationis et gratiae dei cum libero arbitrio* (The Harmony of the Foreknowledge, the Predestination and the Grace of God with Free Choice).

Though his principal writings at Bec were more philosophical while his foremost writings as archbishop were more theological, still we must remember that Anselm himself made no express distinction between philosophy and theology, that at Bec he also wrote two meditations and sixteen prayers, and that his *Cur deus homo* and *De concordia*, in dealing with the weighty theological doctrines of atonement, predestination and grace, incorporate philosophical concepts such as *necessitas praecedens* (preceding necessity) and *necessitas sequens* (subsequent necessity).

Anselm's most famous philosophical work is certainly the *Proslogion*, while his most influential theological work is undoubtedly the *Cur deus homo.* The style of the *Proslogion* imitates that of Augustine in the *Confessiones*, where the soul invokes God as it prayerfully reflects and meditates. By contrast, the *Cur deus homo* is cast in dialogue form because, as Anselm states in I.1, 'issues which are examined by the method of question and answer are clearer, and so more acceptable, to many minds – especially to minds that are slower.' About his aims in the *Proslogion* there is no scholarly consensus. The traditional view holds that he is undertaking the twofold task of demonstrating the existence of God and demonstrating certain truths regarding God's attributes. In carrying out this task, he has recourse to a single consideration (*unum argumentum*), namely, that God is *aliquid quo nihil maius cogitari potest* (something than which nothing greater can be thought). This single consideration gives rise to a single argument form; the logical structure of the reasoning which purports to establish that *quo nihil maius* is actually existent is also the structure of the arguments which conclude that *quo nihil maius* is so existent that it cannot be thought not to exist, is alone existent *per se*, is omnipotent, merciful yet impassable, is supremely just and good, is greater

than can be thought, and so on. According to this interpretation, the *Proslogion* seeks to establish most of the same conclusions that were reached in the earlier *Monologion*, but to establish them more directly, simply and tersely.

The central thrust of the *Cur deus homo* may be discerned from the title: namely, to explain why it was necessary for God, in the person of the Son, to become a man (that is, to become incarnate as a human being (*homo*)). Anselm uses the Latin word *homo* generically and not in the sense of male (*vir*). This fact is seen clearly in *Cur deus homo* II, 8: 'nil convenientius, quam ut de femina sine viro assumat [deus] illum hominem quem quaerimus' 'nothing is more fitting than that God assume from a woman without a male *that* man [human being] about whom we are inquiring'. Though the sense of *homo* varies in accordance with whether Anselm is speaking about a human being or about a human nature, there is no doubt about the meaning of the title: the Son of God assumed *a* human nature, thereby becoming *a* man; he did not assume another man (in other words, assume a human person together with a human nature) as the heretical Nestorians had taught, nor did he become man (in other words, become universal man, by assuming unindividuated human nature as such).

Anselm's detailed theory of satisfaction for sin was in large measure a putative theoretical justification of the institutionalized practices of the confessional and the penitential system as found in the medieval Christian church, which understood every sin to constitute a punishable demerit and to require both the imploring of God's forgiveness and the making of amends for having dishonoured him. Throughout the intricate and sustained reasoning of the *Cur deus homo*, Anselm seeks to show one central truth: 'because only God can make this satisfaction and only a man ought to make it, it is necessary that a God-man make it' (*Cur deus homo* II, 6).

As in the *Cur deus homo*, so also in his other treatises Anselm proceeds insofar as he deems possible, *sola ratione* (by recourse to rational considerations alone). Accordingly, he is rightly called the 'Father of Scholasticism'. He understands *ratio* in a broad sense, broad enough to encompass appeals to experience as well as to conceptual intelligibility. Although the main intellectual influence upon him was Augustine, he is less platonistic than the latter, and the influence of Aristotle's *De interpretatione* and *Categories* (from Boethius' Latin translations) is clearly discernible in his philosophical works.

JASPER HOPKINS

ANTHROPOLOGY, PHILOSOPHY OF

Anthropology, like philosophy, is multifaceted. It studies humans' physical, social, cultural and linguistic development, as well as their material culture, from prehistoric times up to the present, in all parts of the world. Some anthropological subfields have strong ties with the physical and biological sciences; others identify more closely with the social sciences or humanities. Within cultural and social anthropology differing theoretical approaches disagree about whether anthropology can be a science. The question of how it is possible to understand cultures different from one's own, and to transmit that knowledge to others, is central to anthropology because its answer determines the nature of the discipline. Philosophy of anthropology examines the definitions of basic anthropological concepts, the objectivity of anthropological claims and the nature of anthropological confirmation and explanation. It also examines the problems in value theory that arise when anthropologists confront cultures that do not share their own society's standards.

ANTIREALISM

See Intuitionistic logic and antirealism; Realism and antirealism; Scientific realism and antirealism

ANTI-SEMITISM

Anti-Semitism is a form of racism which sees Jews as a dangerous and despicable group in society. It has solid philosophical sources in the work of German idealism which emphasized the distinctiveness of Judaism and how it has been superseded by Christianity. Both Kant and Hegel made a sharp distinction between Judaism and what they regarded as more rational religions, and they questioned the capability of the Jewish people for playing an integral role in the state. Sartre used the notion of anti-Semitism to show how a sense of self-identity is created by the attitudes of others towards the individual and the group. That is, what makes Jews Jews is the fact that there is anti-Semitism, and there is nothing that Jews can do about anti-Semitism. Anti-Semitism is a problem for the anti-Semites themselves; anti-Semitism, by Sartre's account, is in fact an attempted solution to the difficulties of taking free and authentic decisions. Anti-Semitism has played an important role in Jews'

self-definition, and in attitudes to the State of Israel and to the religion of Judaism itself.

APEL, KARL-OTTO (1922–)

The German philosopher Karl-Otto Apel is best known for his wide-ranging 'transcendental pragmatic' approach to a gamut of issues in theoretical and practical philosophy. This approach accords 'argumentative discourse' and its essential normative presuppositions a foundational role within all other philosophical inquiries for which justifiable validity claims are raised, for example epistemology, normative theories of rationality, Critical Theory and ethics. If there are such presuppositions then any interlocutor's communicative intention to waive them will clash with the construal of that debate as rationally meaningful, since it involves the interlocutor in a kind of inconsistency that Apel (like Habermas), drawing on speech-act theory, conceptualizes as a 'performative self-contradiction'. Apel (unlike Habermas) develops this concept into the doctrine of rationally definitive justification (*Letztbegründung*). Apel deserves to be better known as the originator of discourse ethics (*Diskursethik*), whose central contention (that some presuppositions of discourse have universally valid moral content) he developed in the mid-1960s.

MATTHIAS KETTNER

APPLIED ETHICS

Introduction

Applied ethics is marked out from ethics in general by its special focus on issues of practical concern. It therefore includes medical ethics, environmental ethics, and evaluation of the social implications of scientific and technological change, as well as matters of policy in such areas as health care, business or journalism. It is also concerned with professional codes and responsibilities in such areas.

Typical of the issues discussed are abortion, euthanasia, personal relationships, the treatment of nonhuman animals, and matters of race and gender. Although sometimes treated in isolation, these issues are best discussed in the context of some more general questions which have been perennial preoccupations of philosophers, such as: How should we see the world and our place in it? What is the good life for the individual? What is the good society? In relation to these questions, applied ethics involves discussion of fundamental ethical theory, including utilitarianism, liberal rights theory and virtue ethics.

'Applied ethics' and 'applied philosophy' are sometimes used as synonyms, but applied philosophy is in fact broader, covering also such fields as law, education and art, and theoretical issues in artificial intelligence. These areas include philosophical problems – metaphysical and epistemological – that are not strictly ethical. Applied ethics may therefore be understood as focusing more closely on ethical questions. Nevertheless, many of the issues it treats do in fact involve other aspects of philosophy; medical ethics, for example, includes such metaphysical themes as the nature of 'personhood' or the definition of death.

1 Definitions

While the name 'applied ethics' is comparatively new, the idea is not. Philosophy has traditionally concerned itself with questions both of personal morality (what should I do?) and public morality (what is the good society?), but while these questions are fundamental to applied ethics, they could also be said to characterize ethics in general. Applied ethics is therefore distinguished commonly as that part of ethics that gives particular and direct attention to practical issues and controversies.

In the private sphere, ethical issues include, for example, matters relating to the family (see Family, ethics and the), or to close personal relationships (see Friendship), the care of the old or disabled, the raising of the young, particularly where matters of morality are concerned, or personal ethical problems arising for the individual in the workplace. In the public sphere, applied ethics may involve assessing policy in the light of the impact of advances in biomedical technology (see Life and death; Technology and ethics), or assessing international obligations and duties to future generations in the light of environmental problems (see Future generations, obligations to; Population and ethics). The public arena includes, too, a range of issues for the plural society, such as ethnicity or gender in relation to discrimination,

cultural understanding and toleration; more widely still, it may extend to issues of interest also to political philosophy, such as terrorism and the ethics of war. In all these matters, the concern of applied ethics is not only to supply a personal ethical perspective, but also to provide guidelines for public policy.

Applied ethics includes, as well, the area of professional ethics; it examines the ethical dilemmas and challenges met with by workers in the health care field – doctors, nurses, counsellors, psychiatrists, dentists – and by a wide range of workers in other professions including lawyers, accountants, managers and administrators, people in business, police and law enforcement officers. Specific ethical issues such as confidentiality, truth-telling or conflicts of interest may arise in all or any of these areas, and most professions seek to codify their approaches and provide guidance for their members.

2 Theory and practice

Underlying all such issues are questions about justice, rights, utility, virtue and community. The practice of distinguishing between theoretical and applied ethics must, therefore, be treated with some caution. Indeed, some have regarded the term 'applied' as redundant, on the grounds that there cannot be an 'ethics' which is not applied: on the one hand, they argue, theoretical concepts such as rights and justice should not be viewed as mere abstractions; and, on the other, applied ethics should not be detached from its roots in traditional morality. But while it is important to stress this continuity, there are certain characteristic features of applied ethics which mark it out in practice from theoretical ethics. These are (a) its greater attention to context and detail and (b) its more holistic approach – its willingness to link ethical ideals to a conception of human nature and human needs (see Human nature). Thus practitioners of applied ethics may be more willing than proponents of traditional academic moral philosophy to recognize that psychology and sociology, a knowledge of culture and history, the insights of good literature, and even an understanding of humans as biological entities, are all relevant to the determination of moral issues in personal and public life.

The demarcation line between applied and theoretical ethics which this suggests may be drawn at that point on the spectrum of ethics where ethical theory stops short of normative recommendations and confines itself to the analysis of moral concepts such as 'right', 'good', 'responsibility', 'blame' and 'virtue' and to discussion of what might be called the epistemology of ethics – such theories as ethical realism, subjectivism and relativism (see Moral knowledge; Moral realism). This is the area sometimes described as 'meta-ethics'. Drawing the line at this point may be useful so long as it is not allowed to obscure the truth that applied and theoretical ethics are not discrete but lie on a continuum from the particular to the general, the concrete to the abstract.

The ultimate focus of applied ethics may well be entirely particular: the individual case study. And it is this that gives rise to a further characteristic feature of applied ethics: its concern with dilemmas – not necessarily in the hard logical sense of situations in which it is impossible to act rightly because each of two opposite courses of action is either judged to be mandatory or judged to be wrong; but in the looser sense of cases in which a choice between courses of action may be extremely difficult, the arguments on both sides being compelling, and the person who must act being strongly influenced in opposing directions (for example, to sanction drastic medical intervention to save a severely disabled baby which would otherwise die, or to allow nature to take its course). It should be said, though, that choosing between options which are not morally equal is not, strictly speaking, a dilemma, although it is admittedly likely to be emotionally traumatizing, while choosing between moral obligations that are indisputably of equal weight is not a *moral* problem. The question for applied ethics in such cases may well be whether or not the available options are indeed morally equal.

Because it focuses on individual dilemmas, applied ethics must confront the question of universalization, which may also be seen as a 'free rider' problem: many things are judged to be wrong as a result of asking the question, 'What if everyone did that?', even though, in a particular case, it might seem harmless and more convenient for an individual to ignore the rule, while benefiting from the fact that everyone else is following it (see Universalism in ethics). The applied ethicist, like the theoretical moral philosopher, must find a way to deal with this problem, but for the applied ethicist, the problem is bound up with the need to employ what is sometimes called moral casuistry. This ancient science is not necessarily to be despised, for while a secondary meaning of the term 'casuist' is indeed 'sophist' or 'quibbler', it was not originally a term of abuse, but simply meant accepting in a theological context people's desire to work out the 'right answer' to a difficult issue of conscience in a particular set of circumstances.

3 Method

One method of reasoning employed in applied ethics may be compared to that of a designer who starts with a blueprint, but has to adapt it to the

materials to hand and to the situations in which it is required. There is some resemblance in this case to the Hegelian method of dialectical reasoning, as well as to the method of reflective equilibrium favoured by such contemporary writers as Rawls, in which intuitions in response to particular cases are measured against principles, causing them to be revised and their implications for particular cases again reappraised (see Moral justification §2). According to this view of the subject, the method of applied ethics is neither purely deductive nor purely inductive. For others, however, the deductive model is more powerful, and the question to be answered in any particular case is simply *which* (inviolable) principle it falls under. Others again would favour the inductive model, according to which, by clearly seeing what is right in particular cases, it becomes possible to formulate a general principle encompassing these and other particular judgments (see Universalism in ethics).

In general, discussion of ethical theories in applied ethics aims to pursue, in the direction of the highest degree of generality and abstraction, the question of what humans should do. In practice, discussion of theories is often confined to their implications for the resolution of particular problems, since applied ethics characteristically seeks to answer the broad question with a much greater degree of particularity.

4 Critics and opponents

In seeking answers to practical problems, applied ethics runs counter to much recent philosophy. The view that prevailed during the dominance of empiricism and positivism (the greater part of the twentieth century) is that philosophy can have nothing to say about pressing practical problems.

This view is grounded in two important philosophical arguments: (a) Hume's objection to arguments that seek to derive an 'ought' from an 'is' (see Hume, D.); and (b) Moore's argument that to identify moral characteristics with 'natural' or empirical ones is to commit a 'naturalistic fallacy' (see Moore, G.E.; Naturalism in ethics). Both of these arguments must be resisted if applied ethics is to succeed in closing the gap between factual descriptions of situations and moral judgments, and both may partially at least be answered by insisting that some facts 'speak for themselves' – torture, child-murder, genocide, for example.

The argument that facts and values are to be kept apart is, however, less of an obstacle to philosophers outside the English-speaking world; the notion of praxis, for example, is familiar from various continental traditions, including Marxism, the Frankfurt School, and the philosophy of Habermas; while the idea of the philosopher as *engagé* – as concerned with playing a part in the world – is an important part of French existentialist thought, made familiar in the works of Sartre. These sources have, however, produced a different kind of challenge to the notion of applied ethics as an impartial and essentially reason-based approach to ethical issues in society. Objections to the conception of universal moral norms and to foundationalist procedures in reasoning (the 'postmodernist' challenge) are associated with recent developments in Marxist theory, certain feminist approaches to ethics and epistemology, and the deconstructionist movement – schools of thought which may also adopt an analysis of power-structures in society incompatible with belief in individual freedom of action (see Feminism and psychoanalysis; Deconstruction). Supporters of these theoretical positions often make strong claims for the recognition of rights, but this is probably better seen as exploitation of the preconceptions of their opponents, rather than as recognition of universal ethical concepts and human freedom.

Other critiques of traditional ethics may, however, be more sympathetic to applied ethics. On the basis of research revealing the contextuality of many women's responses to ethical dilemmas, some feminist writers, most prominently Carol Gilligan, have argued that women in general are likely to adopt an ethic of care and responsibility to particular others rather than an abstract morality of principles, rights or justice. Such an approach may well seem better adapted to the resolution of 'hard cases' in, for example, health care or social work.

Similarly, the approach known as 'virtue ethics', with its emphasis on seeking the good in particular situations, may seem well adapted to applied ethics, even if its proponents sometimes appear to view it in opposition, regarding their own stand as more objective, and wrongly equating applied ethics with subjectivism and relativism (see Virtue ethics).

Other stereotypes to be rejected are political: applied ethics has typically been associated with vegetarianism, pacifism, feminism and environmentalism. It should be noted, however, that it also includes criticism and evaluation of these positions: defences of meat-eating or animal experiments, scepticism about feminism, and resistance to new 'ecological ethics' are to be found alongside more orthodox publications on library shelves. There is nothing wrong with variety of opinion so long as this is within a broad ethical framework, for it is of the essence of applied philosophy in general to approach individual issues in their own right and not as part of an ideological package-deal.

Applied ethics, then, is part of a whole view of the human condition and takes a broad view of ethical decision-making. Essentially, this is ethical

decision-making seen as practical policy that consciously recognizes the constraints of moral norms, rights and ethical principles capable of commanding universal respect. Where this is accepted, the object of applied ethics is plain: it is to gain clearer perceptions of right and wrong, with a view to embodying these insights in manners and institutions.

5 Historical context

The inception of applied philosophy could well be said to coincide with that of the Western philosophical tradition as a whole, for the first of the early Greek philosophers, Thales (*c*.585 BC), is recorded as having combined his speculative philosophical interests with economic acumen and an interest in legal and political reform. Later schools of philosophy in ancient times – Pythagoreans, Epicureans, Stoics – offered their followers principles for living and even distinctive codes of practice.

For both Plato and Aristotle, ethical and political questions were posed in terms of such notions as the good for man, the ultimate good, or what is good in itself and for its own sake (see PLATO §16; ARISTOTLE §21). Their assumption was that this inquiry led both to a way of life for the individual, and to a conception of the good society. They disagreed about whether this would lead an individual necessarily to live according to the ethical insight thus gained, Aristotle, unlike Plato in his earlier writings, allowing for the intervention of weakness of will to divert the person who has recognized the good from pursuing it (see AKRASIA).

Subsequent philosophers frequently applied their ethical assumptions to particular cases, and saw this, not as a way of fractionizing moral philosophy – making it the science of the particular – but as a route to formulating guiding principles. Aquinas treated a range of practical issues including marriage and the family in *Summa theologiae*, and this tradition was developed further by Suárez and Grotius. Locke wrote on the issue of toleration, Kant on suicide and on the question of whether it is ever right to tell a lie from benevolent motives (see LOCKE, J. §7; TOLERATION; SUICIDE, ETHICS OF). Bentham put forward a complex theory of punishment, even formulating plans for a new type of prison, to be called the 'panopticon'. He also wrote on legal and political reform. Hegel's philosophy included views on the family and on punishment. J.S. Mill's writings on toleration, paternalism and feminism in *On Liberty* continue to be of interest in the present day, as the controversies involved in these areas remain subjects of disagreement and debate (see FEMINISM; PATERNALISM), and Dewey's theories of education exercised enormous practical influence on education systems in the USA and Britain (see EDUCATION, HISTORY OF PHILOSOPHY OF).

The tradition in moral philosophy unsympathetic to applied ethics is in fact of fairly recent origin. It was associated with the dominance of positivism and empiricism in the philosophy of science, and the vogue for linguistic analysis in epistemology. This is a twentieth-century phenomenon and, right up to the closing years of the nineteenth century, a more generous conception of ethics flourished. If a certain myopia on applied issues is recognized amongst philosophers in the English-speaking world, coinciding roughly with the first half of the twentieth century, various explanations may be offered for the gradual return of visual focus. For those with an interest in medical ethics, a research project in Tuskegee in the USA in which a control group with syphilis remained untreated for decades after safe treatment was known to be possible is often cited as a trigger generating widespread discussion of issues such as autonomy, beneficence and nonmaleficence, medical confidentiality, and the ethics of experiments on human subjects (see MEDICAL ETHICS). This case may have been, however, a symptom rather than a cause, for in general medicine moved during those decades from being a practice with little power to influence the natural course of disease, to being a powerful interventionist tool. Whatever the specific cause, then, from roughly this period medical ethics became an arena of critical and controversial discussion.

Again in the USA, the Vietnam War and the protests which it generated are cited as having promoted discussion of a different range of applied issues (civil disobedience, duty to conscience versus duty to society) and as having led in a fairly direct way to the setting up of the Society for Philosophy and Public Affairs and the journal *Philosophy and Public Affairs* (see CIVIL DISOBEDIENCE; CONSCIENCE).

Others, focusing on the applied philosopher's interest in animal welfare, cite the publication of the volume *Animal Liberation* (1975) by Peter Singer as ushering in a new conception of ethics as a practical and possibly even campaigning area (see ANIMALS AND ETHICS §3). Already, too, Rachel Carson's *Silent Spring* (1962) had alerted the general public to many environmental hazards and thus opened the way to an enlarged philosophical perspective in which developments in science and technology and the way in which these were applied by firms and governments to the environment were seen as matters of ethical concern. It was a decade or so later that the internal operations of businesses became matters for ethical scrutiny, prompted by scandals connected with sharp practices such as insider trading.

Finally, it must be said that philosophy itself no doubt provided a spur to the growth of applied ethics. The preoccupation of academic moral philosophy with entirely minor moral issues in a century which had witnessed two world wars and many accompanying gross violations of human rights was too remarkable to pass for long, particularly with wider access to higher education and hence to the hitherto elite and somewhat esoteric pursuit of philosophy.

This account of the rise of contemporary applied ethics raises the question of what kind of study applied ethics is exactly. Is it merely another kind of academic study, or is it committed to the promotion of change in the world? Is it conservative or radical? Reactionary or revolutionary? The answer to this last question is that it can be either. Reflection may make one seek to promote change for the better, but it may also cause one to recoil from change and seek to preserve what is best from the past. The controversial nature of most of the issues involved is itself a spur to their philosophical study, for it is probably true to say that until recently, despite differences of religious or ideological background, a common moral approach could in general be assumed, and accepted norms of moral behaviour could be taken as a starting-point for ethical reasoning. Such moral consensus cannot now be presupposed, and, while absolutist approaches are by no means inconsistent with mainstream philosophical ethics, in practice the defence of an absolute conception of morality against relativistic, subjective and utilitarian approaches is often associated with a religious perspective.

Many writers on applied ethics, however, adopt a secular utilitarian stance. These include the Australian philosopher Peter Singer, and the Oxford philosopher Jonathan Glover, who has written especially in the area of medical ethics (see UTILITARIANISM). R.M. Hare, in *Moral Thinking* (1981), puts forward a prescriptivist theory which combines utilitarianism with Kantian universalizability (see PRESCRIPTIVISM). Also influential is the ethic of care mentioned above, which is often linked to gender differences. Other views include those of the Australian philosopher John PASSMORE, who defends a liberal moral perspective, especially in relation to environmental ethics, and John RAWLS, whose notion of reflective equilibrium combines intuitionism with contract theory (see MORAL JUSTIFICATION §2). Rawls' *A Theory of Justice* (1971) inaugurated a new, more practical approach in ethics, which had implications for economics, law and political theory. Sissela Bokhas has written on the fine texture of issues in public life in *Lying: Moral Choices in Public and Private Life* (1978) and *Secrets* (1984) (see TRUTHFULNESS); Mary Midgley, in *Beast and Man* (1978) and elsewhere, has discussed the relations between humans and other species; and Onora O'Neill has brought a Kantian ethic to bear on the issues of famine and poverty. The debate between communitarians and libertarians about the ethics of capitalism and the role of welfare can also be seen as a part of applied ethics (see COMMUNITY AND COMMUNITARIANISM; MARKET, ETHICS OF THE). The German philosopher, Jürgen HABERMAS, an influential figure both in continental Europe and the English-speaking world, has put forward a notion of consensus as the object of theory expressed in practice.

6 Professional ethics

Similar divisions may reveal themselves in professional ethics, although the idea that there should be special codes of ethics peculiar to particular professions has been current since ancient times, when the Hippocratic oath was required of those engaging in medical practice. Many modern groups, including engineers, nurses and lawyers, have adopted formal codes setting standards of ethical practice for their profession (see PROFESSIONAL ETHICS).

Ethics also plays an increasing role in the training of professionals. Often the preferred approach is through the use of case studies, sometimes fictional, sometimes using videos of actual cases. One problem with the case study approach is its possible negative effect. In stressing that there are at least two sides to many ethical problems, and in presenting ethical theories as giving conflicting outcomes, they may risk generating a facile moral or cultural relativism – the view that there are only opinions, not answers. The use of case studies and discussion based on situational ethics may also tacitly undermine principles (see SITUATION ETHICS). In contrast, some courses aim simply to increase the moral sensitivity of trainees, on the assumption that if this is successful they will go on to make good professional decisions.

7 Are there ethical experts?

Applied ethics does not involve a claim of moral expertise, but often involves collaboration with specialists in practical areas in order to arrive at policy decisions that allow ethical considerations a determining role.

There is now wide acceptance of the principle of ensuring that a philosophical or ethical viewpoint is represented in certain kinds of forums, such as public enquiries, the reports of legislative committees or commissions of inquiry, and hospital ethics

committees. The USA has a President's Commission to report directly on bioethical issues to the US President, the UK has a National Bioethics Committee funded independently of government, while in France there is a French National Committee on Ethical Affairs in Public Debate. In 1985, the Council of Europe created a multidisciplinary body with experts appointed by each member country, now called the Comité Directeur de Bioéthique (CDBI). Canada set up a Royal Commission on New Reproductive Technologies, and the European Parliament commissions advise on scientific and technological policy options. Other countries are following a similar pattern. In addition, the Council of Europe in 1990 began working on a European Convention on biomedical ethics, which would be a legally binding instrument on all countries signing it, the object being ultimately to harmonize European legislation.

Individuals are also used as consultants on public policy issues. In Europe in 1989, Jonathan Glover, in collaboration with nationals of other European countries, produced a report on fertility and the family for the European Commission, while Will Kymlicka has advised on this topic as a member of the Canadian Royal Commission and, in the USA, Arthur Caplan was a member of the President's Task Force on National Health Care Reform. In Britain, the philosopher Mary Warnock was responsible for official reports on the educational needs of children with disabilities and learning difficulties, and on new developments in reproductive medicine and embryology; Bernard Williams played a similar role in relation to pornography and censorship. The debate about euthanasia in the Netherlands has engaged philosophers, lawyers and social theorists. Less happily, a visit by Peter Singer to Germany provoked widespread protest related to the debate on euthanasia and has led to the unpopularity of bioethics in some circles, and a general and unjustified rejection of applied ethics.

Some achievements in these areas may also be recorded; examination of the ethics of clinical trials, for example, particularly in relation to AIDS, led to a total reconceptualization of what clinical trials require, and to a multi-choice system being devised which is both scientifically acceptable and also offers a more acceptable level of choice to patients and physicians.

8 Research in applied ethics

In general, those who fund research regard the gathering of facts, often called the 'generation of new knowledge', as crucial; philosophy, in contrast, appears to involve reflection on facts, while normative philosophy generates proposals for action or policy. Applied ethics offers at its best an opportunity to combine these approaches: for facts to be made the fruitful object of analytic and morally sensitive reflection, and for philosophical inquiry to accept the discipline of the need to take account of the practical framework within which speculation is cast.

Research in applied ethics, then, ideally starts from a perceived problem and is motivated to find a solution to that problem. It is frequently interdisciplinary. A research programme is often inspired by technological progress, for it is this that has placed ethical considerations at the heart of many areas of public debate. Typical of these are the controversies already mentioned surrounding the new technologies of reproduction – embryo research, donation of gametes, surrogate motherhood – which raise questions about the status of the human embryo and the definition of parenthood (see Reproduction and ethics).

Other appropriate areas where ethics impinges on practical inquiry include, for example, the ethical implications of the Human Genome Project, the ethics of confidentiality, insurance in relation to AIDS or inherited disease, the care of the elderly, homelessness, and mental illness (see Genetics and ethics; Medical ethics). One caveat to be noted here, however, is that simply gathering data about what people think is right is sociology, not ethics, applied or otherwise.

9 Institutions

Many research centres have been created in recent decades. Their function is usually to conduct research, to produce publications and to arrange lectures, seminars and conferences on practical issues of ethical concern.

North America has the best-established institutional network. First in the field was the Hastings Center, New York (1969), then the Center for Philosophy and Public Affairs, University of Maryland and the Center for the Study of Ethics in the Professions at the Illinois Institute of Technology (1976), the Center for the Study of Values, University of Delaware (1977), and the Social Philosophy and Policy Center, Bowling Green State University, Ohio (1981). There are now many other centres in universities both in the USA and elsewhere, including, in the UK, the Centre for Philosophy and Public Affairs at the University of St Andrews, the Centre for Medical Law and Ethics at King's College London, and the Social Values Research Centre at the University of Hull. The Netherlands has Bioethics Centres in Utrecht and Maastricht and work in applied ethics in the Scandinavian countries is increasing, with a

strong interest in reproductive ethics in Aarhus, Denmark and in animal welfare issues in Copenhagen. The European Business Ethics Network (EBEN) began with an initiative from Switzerland, and business ethics is also well-established in Spain and Germany. Apart from university-based units, the Society for Applied Philosophy has general interests in most areas of applied ethics and has a broad membership not confined to professional philosophers.

Australia has been a pioneer in many fields of applied ethics: Peter Singer, together with Helga Kuhse, founded the Centre for Human Bioethics (1980) at Monash University, and there are now several other applied ethics centres in Australasia; it is worth noting the particular degree of interest there in environmental ethics, where the issues of species preservation, wilderness and ecological threats such as damage to the ozone layer are of direct concern to residents.

The creation of a Chair of Environmental Ethics at Warsaw University represents the strong interest, partly political in origin, in environmental ethics in the former communist countries of Eastern Europe. Other countries where applied ethics is of growing interest are parts of Southeast Asia, including Thailand and Hong Kong, India, and several African countries.

BRENDA ALMOND

AQUINAS, THOMAS (1224/6–74)

Introduction

Aquinas lived an active, demanding academic and ecclesiastical life that ended while he was still in his forties. He nonetheless produced many works, varying in length from a few pages to a few volumes. Because his writings grew out of his activities as a teacher in the Dominican order and a member of the theology faculty of the University of Paris, most are concerned with what he and his contemporaries thought of as theology. However, much of academic theology in the Middle Ages consisted in a rational investigation of the most fundamental aspects of reality in general and of human nature and behaviour in particular. That vast domain obviously includes much of what is now considered to be philosophy, and is reflected in the broad subject matter of Aquinas' theological writings.

The scope and philosophical character of medieval theology as practised by Aquinas can be easily seen in his two most important works, *Summa contra gentiles* (Synopsis [of Christian Doctrine] Directed Against Unbelievers) and *Summa theologiae* (Synopsis of Theology). However, many of the hundreds of topics covered in those two large works are also investigated in more detail in the smaller works resulting from Aquinas' numerous academic disputations (something like a cross between formal debates and twentieth-century graduate seminars), which he conducted in his various academic posts. Some of those topics are taken up differently again in his commentaries on works by Aristotle and other authors. Although Aquinas is remarkably consistent in his several discussions of the same topic, it is often helpful to examine parallel passages in his writings when fully assessing his views on any issue.

Aquinas' most obvious philosophical connection is with Aristotle. Besides producing commentaries on his works, he often cites Aristotle in support of a thesis he is defending, even when commenting on scripture. There are also in Aquinas' writings many implicit Aristotelian elements, which he had thoroughly absorbed into his own thought. As a convinced Aristotelian, he often adopts Aristotle's critical attitude toward theories associated with Plato, especially the account of ordinary substantial forms as separately existing entities. However, although Aquinas, like other medieval scholars of Western Europe, had almost no access to Plato's works, he was influenced by the writings of Augustine and the pseudo-Dionysius. Through them he absorbed a good deal of Platonism as well – more than he was in a position to recognize as such.

On the other hand, Aquinas is the paradigmatic Christian philosopher-theologian, fully aware of his intellectual debt to religious doctrine. He was convinced, however, that Christian thinkers should be ready to dispute rationally on any topic, especially theological issues, not only among themselves but also with non-Christians of all sorts. Since in his view Jews accept the Old Testament and heretics

the New Testament, he thought Christians could argue some issues with both groups on the basis of commonly accepted religious authority. However, because other non-Christians, 'for instance, Mohammedans and pagans – do not agree with us about the authority of any scripture on the basis of which they can be convinced . . . it is necessary to have recourse to natural reason, to which everyone is compelled to assent – although where theological issues are concerned it cannot do the whole job', since some of the data of theology are initially accessible only in Scripture (*Summa contra gentiles* I.2.11). Moreover, Aquinas differed from most of his thirteenth-century Christian colleagues in the breadth and depth of his respect for Islamic and Jewish philosopher-theologians, especially Avicenna and Maimonides. He saw them as valued co-workers in the vast project of philosophical theology, clarifying and supporting doctrine by philosophical analysis and argumentation. His own commitment to that project involved him in contributing to almost all the areas of philosophy recognized since antiquity, omitting only natural philosophy (the precursor of natural science).

A line of thought with such strong connections to powerful antecedents might have resulted in no more than a pious amalgam. However, Aquinas' philosophy avoids eclecticism because of his own innovative approach to organizing and reasoning about all the topics included under the overarching medieval conception of philosophical Christian theology, and because of his special talents for systematic synthesis and for identifying and skilfully defending, on almost every issue he considers, the most sensible available position.

1 Early years

Thomas Aquinas was born at Roccasecca, near Naples, the youngest son of a large Italian aristocratic family. As is generally true of even prominent medieval people, it is hard to determine exactly when he was born; plausible arguments have been offered for 1224, 1225 and 1226. He began his schooling in the great Benedictine abbey at Monte Cassino (1231–9), and from 1239–44 he was a student at the University of Naples. In 1244 he joined the Dominican friars, a relatively new religious order devoted to study and preaching; by doing so he antagonized his family, who seem to have been counting on his becoming abbot of Monte Cassino. When the Dominicans ordered Aquinas to go to Paris for further study, his family had him abducted en route and brought home, where he was held for almost two years. Near the end of that time his brothers hired a prostitute to try to seduce him, but Aquinas angrily chased her from his room. Having impressed his family with his high-minded determination, in 1245 Aquinas was allowed to return to the Dominicans, who again sent him to Paris, this time successfully.

At the University of Paris, Aquinas first encountered Albert the Great, who quickly became his most influential teacher and eventually his friend and supporter. When Albert moved on to the University of Cologne in 1248, Aquinas followed him there, having declined Pope Innocent IV's extraordinary offer to appoint him abbot of Monte Cassino while allowing him to remain a Dominican.

Aquinas seems to have been unusually large, and extremely modest and quiet. When during his four years at Cologne his special gifts began to be apparent, despite his reticence and humility, Albert assigned the still-reluctant Aquinas his first active part in an academic disputation. Having failed in his efforts to shake his best student's arguments on this occasion, Albert declared, 'We call him the dumb ox, but in his teaching he will one day produce such a bellowing that it will be heard throughout the world'.

In 1252 Aquinas returned to Paris for the course of study leading to the degree of master in theology, roughly the equivalent of a twentieth-century PhD. During the first academic year he studied and lectured on the Bible; the final three years were devoted to delivering in lecture form his commentary on Peter Lombard's *Sentences*, a standard requirement for the degree at that time (see Lombard, P.). Produced in 1253–6, Aquinas' massive commentary (often referred to as the *Scriptum super libros Sententiarum* (Commentary on the Sentences) is the first of his four theological syntheses. It contains much valuable material, but because it is superseded in many respects by his great *Summa contra gentiles* (Synopsis [of Christian Doctrine] Directed Against Unbelievers) and *Summa theologiae* (Synopsis of Theology) the *Scriptum* has not yet been studied as much as it should be.

During that same four-year period, Aquinas produced *De ente et essentia* (On Being and Essence), a short philosophical treatise written for his fellow Dominicans at Paris. Although it owes something to Avicenna's *Metaphysics*, *De ente* is distinctively Aquinas' own, expounding many of the concepts and theses that remained fundamental to his thought throughout his career (see §9 below).

2 *First Paris regency*

In the spring of 1256, Aquinas was appointed regent master (professor) in theology at Paris, a position he held until the end of the academic year 1258–9. *Quaestiones disputatae de veritate* (Disputed Questions on Truth) is the first of his sets of disputed questions and the most important work he produced during those three years. It grew out of his professorship, which obliged him to conduct several formal public disputations each year. *Quaestiones disputatae de veritate* consists of twenty-nine widely ranging Questions, each devoted to some general topic such as conscience, God's knowledge, faith, goodness, free will, human emotions and truth (the first Question, from which the treatise gets its name). Each Question is divided into several Articles, and the 253 articles are the work's topically specific units: for example, q.1, a.9 is 'Is there truth in sense perception?'

The elaborate structure of each of those articles, like much of Aquinas' writing, reflects the 'scholastic method', which, like medieval disputations in the classroom, had its ultimate source in Aristotle's recommendations in his *Topics* regarding cooperative dialectical inquiry. Aquinas' philosophical discussions in that form typically begin with a yes/no question. Each article then develops as a kind of debate. It begins with arguments for the answer opposed to Aquinas' own position; these are commonly, if somewhat misleadingly, called 'objections'. Next come the arguments *sed contra* (but, on the other hand), which are in later works often reduced to a single citation of some generally accepted authority on Aquinas' side of the issue. The *sed contra* is followed by Aquinas' reasoned presentation and defence of his position. This is the master's 'determination' of the question, sometimes called the 'body' of the article (indicated by 'c' in references). An article normally concludes with Aquinas' rejoinders to each of the objections (indicated by 'ad 1', and so on, in references).

Conducting 'disputed questions' was one of the duties of a regent master in theology, but the theology faculty also provided regular opportunities for 'quodlibetal questions', occasions on which a master could, if he wished, undertake to provide replies to any and all questions proposed by members of the academic audience. These occasions were scheduled, for the master's own good, during the two penitential seasons of the church year. Aquinas seems to have accepted this challenge on at least five of the six such occasions occurring during his first regency at Paris, producing *Quaestiones quodlibetales* (Quodlibetal Questions) in which he offers his considered judgment on issues ranging from whether the soul is to be identified with its powers to whether the damned behold the saints in glory.

Aquinas' commentaries on Boethius' *De trinitate* (On the Trinity) and *De hebdomadibus* (sometimes referred to as 'How Substances are Good') are his other philosophically important writings from this period of his first regency. Although several philosophers had commented on those Boethian treatises in the twelfth century, the subsequent influx of Aristotelian works had left them almost universally disregarded by the time Aquinas wrote his commentaries (see BOETHIUS, A.M.S.). No one knows why or for whom he wrote them, but he might well have undertaken these studies for his own edification on topics that were then becoming important to his thought. The *De trinitate* commentary (*Expositio super librum Boethii De trinitate*) presents Aquinas' views on the relationship of faith and reason and on the methods and interrelations of all the recognized bodies of organized knowledge, or 'sciences'. Boethius' *De hebdomadibus* is the *locus classicus* for the medieval consideration of the relation between being and goodness. Dealing with this topic in his commentary on that treatise, Aquinas also produced his first systematic account of metaphysical participation, one of the important Platonist elements in his thought. Participation, he claims, obtains when the metaphysical composition of something includes, as one of the thing's metaphysical components, *X*, which also belongs to something else that is *X* in its own right in a way that is presupposed by the first thing's having *X*. In this way a running man participates in running, a human being participates in animal, and an effect participates in its cause (see also §9 below).

3 Naples and Orvieto: *Summa contra gentiles and biblical commentary*

Aquinas' activities between 1259 and 1265 are not well documented, but he seems definitely to have left his professorship at Paris at the end of the academic year 1258–9. He probably spent the next two years at a Dominican priory in Naples, working on the *Summa contra gentiles*, which he had begun in Paris and which he subsequently finished in Orvieto where, as lector, he was in charge of studies at the Dominican priory until 1265.

Summa contra gentiles is unlike Aquinas' three other theological syntheses in more than one respect. Stylistically, it is unlike the earlier *Scriptum* and the later *Summa theologiae* in that it does not follow the scholastic method; instead, it is written in ordinary prose divided into chapters, like his *Compendium theologiae* (Compendium of Theology) which he seems to have written immediately afterwards (1265–7). More importantly, the *Scriptum*, *Summa theologiae* and the *Compendium* are all contributions to revealed theology, which essentially includes the data of revelation among the starting points of its theorizing. In *Summa contra gentiles*, on the other hand, Aquinas postpones revealed theology to the last (fourth) book, in which he deals with the 'mysteries', the few doctrinal propositions that cannot be arrived at by natural reason alone and that have their sources in revelation only; and he takes these up with the aim of showing that even those propositions 'are not opposed to natural reason' (*Summa contra gentiles* IV.1.3348). He devotes the first three books to developing fully a natural theology, dependent on natural reason of course, but independent of revelation. As developed in Books I–III, this natural theology is able to accomplish a very large part of theology's job, from establishing the existence of God through to working out details of human morality (see also §13 below).

Discussions important for understanding Aquinas' positions in many areas of philosophy are also scattered, not always predictably, among interpretations of the text in his biblical commentaries. During Aquinas' stay in Orvieto and around the time he was writing Book III of *Summa contra gentiles*, on providence and God's relations with human beings, he also produced his *Expositio super Iob ad litteram* (Literal Commentary on Job), one of the most fully developed and philosophical of his biblical commentaries, rivalled in those respects only by his later commentary on Romans. The body of the Book of Job consists mainly of the speeches of Job and his 'comforters'. Aquinas sees those speeches as constituting a genuine debate, almost a medieval academic disputation (determined in the end by God himself), in which the thought develops subtly, advanced by arguments. His construal of the argumentation is ingenious, the more so because twentieth-century readers have tended to devalue the speeches as tedious reiterations of misconceived accusations countered by Job's slight variations on the theme of his innocence.

Aquinas' interpretation of the book's subject is also unlike the modern view, which supposes it to be the biblical presentation of the problem of evil, raised by a good God's permitting horrible suffering to be inflicted on an innocent person. Aquinas seems scarcely to recognize that Job's story raises doubts about God's goodness. As he interprets it, the book explains the nature and operations of divine providence, which he understands as compatible with permitting bad things to happen to good people. As Aquinas sees it:

> If in this life people are rewarded by God for good deeds and punished for bad, as Eliphaz [one of the comforters] was trying to establish, it apparently follows that the ultimate goal for human beings is in this life. But Job means to rebut this opinion, and he wants to show that the present life of human beings does not contain the ultimate goal, but is related to it as motion is related to rest, and a road to its destination.
>
> (*Expositio super Iob ad litteram* 7: 1–4)

The things that happen to a person in this life can be explained in terms of divine providence only by reference to the possibility of that person's achieving the ultimate goal of perfect happiness, the enjoyment of union with God in the afterlife.

In discussing Job's lament that God doesn't hear his prayers, Aquinas says that Job has that impression because God sometimes 'attends not to a person's pleas but rather to his advantage. A doctor does not attend to the pleas of the invalid who asks that the bitter medicine be taken away (supposing that the doctor doesn't take it away because he knows that it contributes to health). Instead, he attends to the patient's advantage; for by doing so he produces health, which the sick person wants most of all'. In the same way, God sometimes permits a person to suffer despite prayers for deliverance, because he knows that those sufferings are helping that person achieve what he or she wants most of all (*Expositio super Iob ad litteram* 9:16).

4 *Rome: disputed questions, Dionysius and the* Compendium

In 1265 Aquinas went from Orvieto to Rome, having been appointed to establish a Dominican *studium* (something like a twentieth-century college) and to serve as regent master there. This Roman period of his career, which lasted until 1268, was particularly productive. Some of his major works dating from 1265–8 are just what would have been expected of a regent master in theology, in particular, three sets of disputed questions, *Quaestiones disputatae de potentia* (Disputed Questions on [God's] Power), *Quaestio disputata de anima* (Disputed Question on the Soul) and *Quaestio disputata de spiritualibus creaturis* (Disputed Question on Spiritual Creatures). In the earliest of these, *De*

potentia, there are eighty-three Articles grouped under ten Questions; the first six questions are on divine power, while the final four are on problems associated with combining the doctrine of Trinity with God's absolute simplicity. The much shorter *De anima* is concerned mainly with metaphysical aspects of the soul, concluding with some special problems associated with the nature and capacities of souls separated from bodies (Articles 14–21). The eleven articles of *De spiritualibus creaturis* again address many of those same concerns but also go on to some consideration of angels as another order of spiritual creatures besides human beings, whose natures are only partly spiritual.

During this same period, or perhaps while he was still at Orvieto, Aquinas wrote a commentary on the pseudo-Dionysian treatise *De divinis nominibus* (On the Divine Attributes), a deeply Neoplatonist account of Christian theology dating probably from the sixth century. Aquinas, like everyone else at the time, believed that it had been written in the apostolic period by the Dionysius who had been converted by St Paul. For that reason, and perhaps also because he had first studied the book under Albert at Cologne, it had a powerful influence on Aquinas' thought. Very early in his career, while he was writing his *Scriptum*, he thought Dionysius was an Aristotelian (*Scriptum* II, d.14, q.1, a.2), but while writing the commentary on this text he realized that its author must have been a Platonist (*Expositio super librum Dionysii de divinis nominibus*, prooemium; *Quaestiones disputatae de malo* 16.1, ad 3). His commentary, which makes clear sense of a text that is often obscure, may, like his commentaries on Boethius, have been written for his own purposes rather than growing out of a course of lectures. In any case, his study of Dionysius is one of the most important routes by which Platonism became an essential ingredient in his own thought.

The *Compendium theologiae* (Compendium of Theology), already mentioned in connection with *Summa contra gentiles*, was once thought to have been written much later and to have been left incomplete because of Aquinas' death. However, its similarity to *Summa contra gentiles* not only in style but also in content has lately led many scholars to assign it to 1265–7. Among Aquinas' four theological syntheses, the *Compendium theologiae* is unique in the brevity of its discussions and in having been organized around the 'theological virtues' of faith, hope and charity. Had it been completed, it might have provided a novel reorientation of the vast subject matter of medieval theology, but Aquinas wrote only ten short chapters of the second section, on Hope, and none at all of the third section, on Charity. He did complete the first section on Faith, but since most of the 246 chapters in the section simply provide much briefer treatments of almost all the theological topics Aquinas had already dealt with in *Summa contra gentiles*, the *Compendium* as he left it seems important mainly as a precis of material that is developed more fully in the other work (and in *Summa theologiae*).

5 Rome: Aristotelian commentary

While some of Aquinas' prodigious output in Rome from 1265–8 is, broadly speaking, similar to work he had already done, it also includes two important innovations, one of which is the first of his twelve commentaries on works of Aristotle. At the beginning of this commentary on *De anima* (*Sententia super de anima*), his approach is still a little tentative and (for Aquinas) unusually concerned with technical details. These features of the work once led scholars to describe the commentary on the first book of *De anima* as a *reportatio* (an unedited set of notes taken at his lectures), or even to ascribe this first third of Aquinas' commentary to another author. However, Gauthier has argued persuasively that the difference between the commentary's treatments of Book I and of Books II and III of *De anima* is explained by differences between the books themselves, and that in fact none of Aquinas' commentaries on Aristotle resulted from lectures he gave on those books. Discrepancies within this work, the first of Aquinas' Aristotelian commentaries, are likely to be at least in part a consequence of the fact that he was finding his way into this new sort of enterprise, at which he quickly became very adept. In a recent volume of essays on Aristotle's *De anima*, Martha Nussbaum describes Aquinas' work as 'one of the very greatest commentaries on the work' and 'very insightful'. T.H. Irwin, a leading interpreter of Aristotle, acknowledges that at one point in the *Sententia libri Ethicorum* (Commentary on Aristotle's *Nicomachean Ethics*) Aquinas 'actually explains Aristotle's intention more clearly than Aristotle explains it himself'. Such judgments apply pretty generally to Aquinas' Aristotelian commentaries, all of which are marked by his extraordinary ability as a philosophical commentator to discern a logical structure in almost every passage he examines in every sort of text: not only Aristotle's but also those of others, from Boethius to St Paul.

Since commenting on Aristotle was a regular feature of life for a member of a medieval arts faculty but never part of the duties of an academic theologian, Aquinas' many Aristotelian commentaries were technically extra-curricular and therefore an especially impressive accomplishment for someone who was already extremely busy. Some scholars, admiring Aquinas' achievements in general

but focusing on the fact that his professional career was entirely in the theology faculty, have insisted on classifying only the Aristotelian commentaries as philosophical works. Certainly these commentaries are philosophical, as purely philosophical as the Aristotelian works they elucidate. However, Aquinas wrote these commentaries not only to make good philosophical sense of Aristotle's very difficult texts but also, and more importantly, to enhance his own understanding of the topics Aristotle had dealt with. As he remarks in his commentary on *De caelo*, 'the study of philosophy has as its purpose to know not what people have thought, but rather the truth about the way things are' (*Sententia super libros de caelo et mundo* I.22.228), and he believed that the theologian's attempt to understand God and everything else in relation to God was the fundamental instance of the universal human drive to know the truth about the way things are. Moreover, his view of the best way of making intellectual progress in general looks very much like the age-old method of philosophy: 'But if any people want to write back against what I have said, I will be very gratified, because there is no better way of uncovering the truth and keeping falsity in check than by arguing with people who disagree with you' (*De perfectione spiritualis vitae* 26) (see ARISTOTLE).

6 *Rome:* Summa theologiae

The other important innovation from Aquinas' three-year regency in Rome is *Summa theologiae*, his greatest and most characteristic work, begun in Rome and continued through the rest of his life. *Summa theologiae*, left incomplete at his death, consists of three large Parts. The First Part (Ia) is concerned with the existence and nature of God (Questions 1–43), creation (44–9), angels (50–64), the six days of creation (65–74), human nature (75–102) and divine government (103–19). The Second Part deals with morality, and in such detail that it is itself divided into two parts. The first part of the Second Part (IaIIae) takes up human happiness (Questions 1–5), human action (6–17), the goodness and badness of human acts (18–21), passions (22–48) and the sources of human acts: intrinsic (49–89) and extrinsic (90–114). The second part of the Second Part (IIaIIae) begins with the three theological virtues and corresponding vices (Questions 1–46), goes on through the four 'cardinal virtues' and corresponding vices (47–170) and ends with special issues associated with the religious life (171–89). In the Third Part, Aquinas deals with the incarnation (Questions 1–59) and the sacraments (60–90), breaking off in the middle of his discussion of penance.

Aquinas thought of *Summa theologiae* as a new kind of textbook of theology, and its most important pedagogical innovation, as he sees it, is in its organization. He says he has noticed that students new to theology have been held back in their studies by several features of the standard teaching materials, especially 'because the things they have to know are not imparted in an order appropriate to a method of teaching': an order he proposes to introduce. It may well have been his enthusiasm for this new approach that led him to abandon work on his quite differently organized *Compendium theologiae*, and his natural preoccupation during this period with the writing of *Summa theologiae* Ia may also help to account for the fact that his other work of that time shows a special interest in the nature and operations of the human soul, the subject matter of Questions 75–89 of Ia (see §13 below).

7 *Second Paris regency*

In 1268 the Dominican Order again assigned Aquinas to the University of Paris, where he was regent master for a second time until, in the spring of 1272, all lectures at the university were canceled because of a dispute with the bishop of Paris. The Dominicans then ordered Aquinas to return to Italy.

Among the astounding number of works Aquinas produced in those four years is the huge Second Part of *Summa theologiae* (IaIIae and IIaIIae), nine Aristotelian commentaries, a commentary on the pseudo-Aristotelian *Liber de causis* (which, as Aquinas was the first to realize, is actually a compilation of Neoplatonic material drawn from Proclus), sixteen biblical commentaries and seven sets of disputed questions (including the set of sixteen *Quaestiones disputatae de malo* (Disputed Questions On Evil), the sixth of which provides his fullest discussion of free choice). His literary productivity during this second regency is the more amazing because he was at the same time embroiled in various controversies.

Sending Aquinas back to Paris in 1268 seems to have been, at least in part, his order's response to the worrisome movement of 'Latin Averroism' or 'radical Aristotelianism', then gaining ground among members of the arts faculty who were attracted to interpretations of Aristotle found in the commentaries of Averroes. However, only two of his many writings from these years seem to have obvious connections with the Averroist controversy. One of these, his treatise *De unitate intellectus, contra Averroistas* (On [the Theory of] the Unicity of Intellect, against the Averroists) is an explicit critique and rejection of a doctrine distinctive of the movement; the theory, as Aquinas describes it, that the aspect of the human mind 'that Aristotle calls the possible intellect ... is some sort of

substance separate in its being from the body and not united to it in any way as its form; and, what is more, that this possible intellect is one for all human beings' (*De unitate intellectus*, prooemium). After briefly noting that this view's incompatibility with Christian doctrine is too obvious to warrant discussion at any length, Aquinas devotes the entire treatise to showing that 'this position is no less contrary to the principles of philosophy than it is to the teachings of the Faith', and that it is even 'entirely incompatible with the words and views' of Aristotle himself (*De unitate intellectus*, prooemium).

Besides the unicity of intellect, the other controversial theory most often associated with thirteenth-century Averroism is the beginninglessness of the universe. In many of his works Aquinas had already considered the possibility that the world had always existed, skilfully developing and defending the bold position that revelation alone provides the basis for believing that the world began to exist, that one cannot prove either that the universe must or that it could not have begun, and that a world both beginningless and created is possible (although, of course, not actual). The second of Aquinas' Parisian treatises that is plainly relevant to Averroism is *De aeternitate mundi, contra murmurantes* (On the Eternity of the World, against Grumblers), a very short, uncharacteristically indignant summary of his position. Aquinas could not complain that Aristotle had been misinterpreted regarding the eternity of the world; after initially supposing this to be the case, he had become convinced that Aristotle really did think he had proved that the world must have existed forever. Aquinas' position on this issue did not distance him enough from the Averroists in the view of their contemporary 'Augustinian' opponents, most notably the Franciscans BONAVENTURE and Pecham. In fact, the 'Grumblers' against whom Aquinas directed this treatise were probably not so much the Averroists in the arts faculty as those Franciscan theologians who maintained that they had demonstrated the impossibility of a beginningless world.

Aquinas' principled dissociation on this point from some important Franciscans must have helped to make his second Paris regency much more troubled than his first. In disputations conducted in Paris in 1266–7, the Franciscan master William of Baglione implicated Aquinas' views in the propositions he attacked, claiming that things Aquinas was saying encouraged the two heretical Averroist theses denounced by Bonaventure, namely the eternity of the world and the unicity of the intellect. It has also been persuasively argued that Aquinas' *De aeternitate mundi* was directed in particular against his Franciscan colleague in theology, John Pecham. It seems, then, that Aquinas' development of a distinctly philosophical theology – which, like Albert's, was more Aristotelian than Augustinian – was dividing him from his colleagues in the Paris faculty of theology during these years. It may also have been bringing him closer to the philosophers in the arts faculty.

8 Last days

In June 1272 the Dominicans ordered Aquinas to leave Paris and go to Naples, where he was to establish another *studium* for the order and to serve as its regent master. Except for some interesting collections of sermons (originally preached in his native Italian dialect), the works dating from this period – two Aristotelian commentaries and the Third Part of *Summa theologiae* – were left unfinished. On or about 6 December 1273, while he was saying mass, something happened to Aquinas that left him weak and unable to go on writing or dictating. He himself saw the occasion as a special revelation. When Reginald of Piperno, his principal secretary and longtime friend, tried to persuade him to return to work on the Third Part of *Summa theologiae*, he said, 'Reginald, I can't'. And when Reginald persisted, Aquinas finally said, 'Everything I've written seems like straw by comparison with what I have seen and what has been revealed to me'. He believed that he had at last clearly seen what he had devoted his life to figuring out and, by comparison, all he had written seemed pale and dry. Now that he could no longer write, he told Reginald, he wanted to die. Soon afterwards he did die, on 7 March 1274 at Fossanuova, Italy, on his way to the Council of Lyons, which he had been ordered to attend.

9 Metaphysics

Every part of Aquinas' philosophy is imbued with metaphysical principles, many of which are recognizably Aristotelian. Consequently, concepts such as potentiality and actuality, matter and form, substance, essence, accident and the four causes – all of which are fundamental in Aquinas' metaphysics – should be considered in their original Aristotelian context (see ARISTOTLE §11). He invokes such principles often, and he employs them implicitly even more often. Two of his earliest writings – *De principiis naturae* (On the Principles of Nature) and especially *De ente et essentia* (On Being and Essence) – outline much of his metaphysics, almost as if they had been designed to provide guidelines for the development of his philosophy. Perhaps the most important thesis argued in *De ente* is the one that became known as 'the real distinction', Aquinas' view that the essence of any created

thing is really, not just conceptually, distinct from its existence. Metaphysically speaking, corporeal beings are composites of form and matter, but all creatures, even incorporeal ones, are composites of essence and existence. Only the first, uncreated cause, God, whose essence is existence, is absolutely simple.

Except for his commentary on Aristotle's *Metaphysics*, Aquinas devoted no mature treatise to metaphysics itself. However, since he considers metaphysics to be the science of being considered generally (*ens commune*), and since he argues that being itself is first of all God himself and that all being depends on God, his philosophy does begin with metaphysics insofar as the most systematic presentations of his thought (in *Summa contra gentiles* and *Summa theologiae*) start with the investigation of God-in-himself considered as the foundation of the nature and existence of everything (see for example, *Summa contra gentiles* III.25; *Expositio super librum Boethii de trinitate* V.4, VI.1; §14 below).

Being, Aquinas says, is intellect's most fundamental conception, 'inherently its most intelligible object and the one in which it finds the basis of all conceptions . . . . Consequently all of intellect's other conceptions must be arrived at by adding to being . . . insofar as they express a mode of being which is not expressed by the term "being" itself' (*Quaestiones disputatae de veritate* 1.1c). There are, he claims, just two legitimate ways of making such additions. The first results in the ten Aristotelian Categories, each of which is a 'specified [or specific] mode of being' – substance, quantity, quality and the rest. The results of 'adding to being' in the second way are less familiar. Aquinas takes them to be five modes of being that are entirely general, characterizing absolutely every being. That is, being, wherever and however instantiated, exhibits these five modes, which transcend the Categories because they are necessary modes of all specified being: thing (*res*), one, something (*aliquid*), good, true. These five, together with being itself, are the 'transcendentals', predicable correctly (if sometimes a little oddly) of absolutely anything that is. 'Good' and 'true' are the philosophically interesting cases, because some beings are obviously not good and because 'true' seems applicable only to propositions.

The claim that all beings are true depends on taking 'true' in the sense of 'genuine', as in 'true friend', a sense that had been explored in detail by Anselm of Canterbury. In Anselm's view, any being is true in this sense to the extent to which it agrees with the divine idea of such a thing (and is otherwise false, but only to some extent). Absolutely every thing that is agrees to some extent with the divine idea that is an ingredient in its causal explanation. Propositions are true if they correspond to the way things are in the world; things in the world are true if they correspond to what is in the mind, God's mind first, ours derivatively. So, Aquinas says, 'in the soul there is a cognitive and an appetitive power. The word "good", then, expresses the conformity of a being to appetite (as is said at the beginning of the *Ethics*: "The good is what all desire"). The word "true", however, expresses the conformity of a being to intellect' (*Quaestiones disputatae de veritate* 1.1c).

The central thesis of Aquinas' meta-ethics grows out of this theory of the transcendentals. The thesis is the metaphysical principle that the terms 'being' and 'good' are the same in reference, differing only in sense (*Summa theologiae* Ia.5.1). What all desire is what they take to be the good, and what is desired is at least perceived as desirable (see for example, *Summa contra gentiles* I.37; III.3). Desirability is thus an essential aspect of goodness. If a thing of a certain kind is genuinely desirable as a thing of that kind, it is desirable to the extent to which it is perfect of that kind: a complete specimen, free from relevant defect. But a thing is perfect of its kind to the extent to which it has actualized its specifying potentialities, the potentialities that differentiate its species from other species in the same genus. So, Aquinas says, a thing is desirable as a thing of its kind and hence good of that kind to the extent to which it is actualized and in being (*Summa theologiae* Ia.5.1). Generally, then, 'being' and 'goodness' have the same referent: the actualization of specifying potentialities. The actualization of a thing's specifying potentialities to at least some extent is on the one hand its existence as such a thing; it is in this sense that the thing is said to have being. However on the other hand, the actualization of a thing's specifying potentialities is, to the extent of the actualization, that thing's being whole, complete, free from defect: the state all things are naturally aimed at. It is in this sense that the thing is said to have goodness (see for example *Summa theologiae* IaIIae.1.5; 94.2; *Summa contra gentiles* III.3; *Quaestiones disputatae de veritate* 21.1–2.)

Aquinas' concept of analogy is important to his thought, though perhaps not so important as it has sometimes been made to seem. It is often presented, correctly, in terms of analogical predication. However, his concept of analogy can be explained at a more fundamental level in connection with causation. Setting aside 'accidental' causation – for example, a gardener's uncovering buried treasure – Aquinas thinks that efficient causation always involves an agent (*A*), a patient (*P*), and a form (*f*). In non-accidental efficient causation, *A* antecedently has *f*, somehow. *A*'s exercising causal power on *P* brings about *f* in *P*, *somehow.* Thus the efficient cause is *A*'s acting (or exercising a power it has), and the effect is

P's having *f*. The fact that *A* and *P* can have *f* in several different ways is what is brought out in '*somehow*'. The paradigm – straightforward efficient causation – is the kind Aquinas calls *univocal*: cases in which first *A* and then *P* have *f* in just the same way, and in which *f* can therefore be predicated truly of each in just the same sense. The metal hotplate and the metal kettle bottom resting on it are both called hot univocally: the form heat in these two causally related objects is the same specifically and differs only numerically.

However, Aquinas also recognizes two kinds of non-univocal efficient causation. The first – *equivocal* causation – characterizes cases in which there is no obvious respect in which to say that the *f* effected in *P* is found antecedently in *A*, and yet there is a natural causal connection (as there standardly is an etymological explanation for equivocal predication). If *A* is solar power and its effect is the hardening (*f*) of some clay (*P*), then obviously the sun's power is not itself hard, as the clay is. To say what it is about solar power that hardens clay will not be as easy as explaining the heating of the kettle, and yet the hardening of the clay must, somehow, be brought about by that power. In such a case, *A* has *f* only in the sense that *A* has the power to bring about *f* in *P*.

Second, *analogical* causation occurs when, for instance, a blood sample (*P*) is correctly labelled 'anaemic', although of course the blood itself doesn't have anaemia and cannot literally be anaemic. The physiology of the sample's donor (*A*) brings about a condition (*f*) in the sample that is an unmistakeable sign of anaemia in *A*, thus justifying that (analogical) labeling of the sample. For theological purposes, Aquinas is interested not in natural analogical causation but rather in the artificial kind: the kind that involves ideas and volitions, the artisan's kind. 'In other agents [the form of what is to be brought about occurs antecedently] in keeping with *intelligible* being, as in those agents that act through intellect – the way a likeness of the house exists antecedently in the builder's mind' (*Summa theologiae* Ia.15.1c). Since the status of entirely univocal causation depends on there being a merely numerical difference between the *f* in *A* and the *f* in *P*, an intellective agent effecting its ideas is obviously not a univocal cause. But neither is this difference between the antecedent *f* and the consequent *f* so wide as to constitute equivocal causation. In fact, the kind of association between the idea and its external manifestation is closer than the kind found in natural analogical causation; and since, in Aquinas' view, 'the world was brought about not by chance but by God acting through intellect . . . it is necessary that there be a form in the divine mind, a form in the likeness of which the world was made' (*Summa theologiae* Ia.15.1c). God, then, is the non-univocal, non-equivocal, intellectively analogical efficient cause of the world (see CAUSATION; GOD, CONCEPTS OF).

10 Philosophy of mind

Aquinas' philosophy of mind is part of his more general theory of soul, which naturally makes use of his metaphysics. Obviously he is not a materialist – most obviously because God, the absolutely fundamental element of his metaphysics, is in no way material. Aquinas classifies every thing other than God as either corporeal or incorporeal (spiritual); he sometimes calls purely spiritual creatures – such as angels – 'separated substances' because of their essential detachment from body of any sort. However, this exhaustive division is not perfectly exclusive because human beings, simply by virtue of the human soul, must be classified not as simply corporeal but also as spiritual in a certain respect.

Merely having a soul of some sort is not enough to give a creature a spiritual component, however. Every animate creature has a soul (*anima*) – 'soul is what we call the first principle of life in things that live among us' (*Summa theologiae* Ia.75.1c) – but neither plants nor nonhuman animals are in any respect spiritual. Aquinas holds that even the merely nutritive soul of a plant, or the nutritive + sensory soul of a beast, is like the soul of a human being in being the *form* of a body. No soul, no first principle of life, can be *matter*. On the other hand, any vegetable or animal body has the life it has only in virtue of being a body whose special organization confers on it natural potentialities: that is, in virtue of the substantial form that makes it actually be such a body. Therefore, the first principle of life in a living nonhuman body, its soul, is no bodily part of that body but is rather its form, one of the two metaphysical components of the composite of matter and form that every body is. For plants and beasts, unlike humans, the form that is the soul goes out of existence when the composite dies, and it is in that sense that the souls of plants and beasts are not spiritual.

Only the soul of a human being is analysed as nutritive + sensory + *rational*. Aquinas thinks of this soul not as three nested, cooperating forms, but as the single substantial form that gives a human being its specifically human mode of existence. (In defending this thesis of 'the unicity of substantial form', Aquinas differed from most of his contemporaries.) He often designates this entire substantial form by its distinctively human aspect of rationality. He also thinks that the human soul, unlike the souls of plants and beasts, is subsistent: that is, it continues to exist after separating from the body in death. He

says, for example: 'It is necessary to say that that which is the principle of intellective activity, what we call the soul of a human being, is an incorporeal, subsistent principle' (*Summa theologiae* Ia.75.2c). The human soul, just because it is distinctively mind (the principle of intellective activity), must therefore be described not only as incorporeal but also as subsistent.

It may seem impossible for Aquinas' account to accommodate the claim that souls persist and engage in mental acts after the death of the body. If the separated soul is a form, what is it a form of? Aquinas is not a universal hylomorphist; unlike some of his contemporaries, he does not think that there is 'spiritual matter' that angels or disembodied souls have as one of their components, but rather that they are separated forms that configure no matter at all. Thus when he claims that the soul exists apart from the body, he seems to be holding the view that there can be a form with nothing of which it is the form. Moreover, Aquinas thinks that an angel or the soul separated from the body engages in mental activity. However, a form seems not to be the sort of thing that enages in acts of any sort, and so it appears that even if there were some way to explain the existence of the soul apart from the body, its acting could not be explained.

In this connection, it is helpful to examine Aquinas' broader view of form. The world is ordered metaphysically in such a way that at the top of the universal hierarchy there are forms – God and angels – that are not forms *of* anything. Near the bottom of the hierarchy are forms that configure matter but cannot exist in their own right, apart from the corporeal composites they inform. The forms of inanimate things and of animate, non-rational things are of that sort. Those forms inform matter, but when the resultant composites cease to exist, those forms also cease to exist. In the middle – 'on the borderline between corporeal and separated [that is, purely spiritual] substances' – are human souls, the metaphysical amphibians (*Quaestio disputata de anima* 1c). Like angels, human souls are subsistent, able to exist on their own; but, like the forms of inanimate things, human souls configure matter.

Seeing the soul in this light helps to explain some of what is initially puzzling in Aquinas' account. The human soul has a double character. On the one hand, unlike the forms of other material things, it is created by God as an individual entity in its own right, able to exist by itself as do purely immaterial angels. On the other hand, like the form of any corporeal thing, it exists in the composite it configures, and it comes into existence only with that composite, not before it (see SOUL, NATURE AND IMMORTALITY OF THE).

11 Theory of knowledge

Nature, Aquinas thinks, must be arranged so as to enable human beings in general to satisfy their natural desire to know (*Sententia super Metaphysicam* I.1.3–4). His view of the arrangement actually provided seems at first too tight to be true, involving some sort of formal identity between the extra-mental object (*O*) and the cognizing faculty (*F*) in its actually cognizing *O*. However, Aquinas takes that (Aristotelian) identity-claim to mean only that the form of *O* is somehow *in F* (*Summa theologiae* Ia.85.2, ad 1). *O*'s form comes to be in *F* when *F* receives *species*, either sensory or intellective, of *O*. These species may be thought of as encodings of *O*'s form. If *O* is a particular corporeal object – an iron hoop, for instance – then in *O* itself *O*'s form informs matter to produce an iron hoop of just those dimensions at just that spatio-temporal location. (In Aquinas' account of individuation, it is matter that is 'designated' or 'determinate' in this way that individuates *O*'s form: see for example *De ente et essentia* 2.) But when the appropriately encoded form is received in an external sense faculty *F* (which uses a bodily organ), then, even though it is received *materially* in *F*'s matter, it is nonetheless received differently from its reception in the matter of the hoop. The imposition of the form on the matter of the sense organ constitutes an 'intentional' or 'spiritual' reception of the form, contributing to a cognition of the hoop rather than metaphysically constituting a new, individuated matter–form composite.

Sensory species received in external senses are standardly transmitted to 'internal senses', the organs for which, Aquinas thought, must be located in the brain. Among the most important of these for purposes of cognition are 'phantasia' and 'imagination' (although Aquinas usually treats imagination as part of the power of phantasia). Phantasia and imagination produce and preserve 'phantasms', the sensory data that are necessary preconditions for intellective cognition. Imagination and phantasia are also indispensable to conscious sensory cognition. In Aquinas' view, sensible species themselves are not the objects of cognition, and what he says about phantasia suggests that having sensible species isn't sufficient for having sensory cognition. *O* itself, currently having a natural effect on the external senses, is consciously sensed because phantasia has processed *O*'s sensible species into phantasms.

The form presented in a phantasm has of course been stripped of its original, individuating matter, but a phantasm of *O* remains particularized as a phantasm in virtue of having been received in the *different* matter of phantasia's organ, while remaining recognizably the form of *O* because of the details of

O that are preserved in it. However, cognition of *O* as an iron hoop is conceptual, intellective cognition, for which phantasms are only the raw material.

In intellect itself, Aquinas distinguishes two Aristotelian 'powers'. The first is *agent intellect*, the essentially active or productive aspect of intellect, which acts on phantasms in a way that produces 'intelligible species'. These constitute the primary contents of intellect, stored in *possible intellect*, intellect's essentially receptive aspect. 'Through intellect it is natural for us to have cognition of natures. Of course, [as universals] natures do not have existence except in individuating matter. It is natural for us to have cognition of them, however, not as they are in individuating matter but as they are abstracted from it by intellect's consideration', the work of agent intellect, producing intelligible species (*Summa theologiae* Ia.12.4c). The intelligible species of *O* are unlike sensory species of it in that they are only universals, which occur as such only in possible intellect: for example, round, metallic, iron hoop. These 'universal natures' are not only received in the intellective faculty *F*, the possible intellect, but are also of course used regularly as the devices indispensable for intellective cognition of corporeal reality: 'Our intellect both abstracts intelligible species from phantasms, insofar as it considers the natures of things universally, and yet also has intellective cognition of them [the things] in the phantasms, since without attending to phantasms it cannot have intellective cognition of even those things whose [intelligible] species it abstracts' (*Summa theologiae* Ia.85.1, ad 5). It is in this way that 'in intellection we can have cognition of such [particular, corporeal, composite] things in universality, which is beyond the faculty of sense' (*Summa theologiae* Ia.12.4c).

Thus both sense and intellect have cognition of *O*, a particular corporeal thing. However, sense has cognition of *O* only in its particularity (*Sententia super Posteriora analytica* II.20.14). Further, an individual intellect that happened to have the concept 'iron hoop' would have cognition only of a universal nature that happened to be instantiated in *O*, and not also of any instantiation of that nature – unless that intellect were also attending to phantasms of *O*. It is as a result of this attending that intellect also cognizes *O* itself, but as exemplifying a universal, for example, as an iron hoop (*Summa theologiae* Ia.85.5c; *Sententia super de anima* II.12.377).

Although intellect regularly has cognition of a corporeal particular in the way described, its proper object, Aquinas says, is that particular's universal nature, or 'quiddity'. Intellect's 'first operation', then, is its cognition of a universal, its proper object (although as we have seen, agent intellect's abstracting of intelligible species is a necessary step on the way to the cognition of the quiddities of things). Aquinas sometimes calls this first operation 'understanding'. However, *scientia*, which is one of the last operations of intellect, a pinnacle of intellective cognition, also has the natures of things as its objects (see below). Universal natures, the proper objects of intellect's first operation and the objects of the culminating theoretical knowledge of nature, must then be thought of as proper objects of both the beginning and the culmination of intellective cognition. What is cognized in an unanalysed way in the first operation of the intellect – for example, *animal* – is in scientific cognition analysed into the essential parts of its nature – *sensitive animate corporeality* – which are themselves comprehended in terms of all their characters and capacities. In theory, in potentiality, the culminating cognitive state is all that could be hoped for: 'if the human intellect comprehends the substance of any thing – a rock, for example, or a triangle – *none* of the intelligible aspects of that thing exceeds the capacity of human reason' (*Summa contra gentiles* I.3.16).

Intellect's 'second operation' is the making of judgments, affirming by propositionally 'compounding' with one another concepts acquired in the first operation, or denying by 'dividing' them from one another. At every stage past initial acquisition, the cognition of quiddities will partially depend on this second operation, and on reasoning as well: 'the human intellect does not immediately, in its first apprehension, acquire a complete cognition of the thing. Instead, it first apprehends *something* about it – that is, its quiddity, which is a first and proper object of intellect; and *then* it acquires intellective cognition of the properties, accidents, and dispositions associated with the thing's essence. In doing so it has to compound one apprehended aspect with another, or divide one from another, and proceed from one composition or division to another, which is reasoning'. This is sometimes called intellect's third operation (*Summa theologiae* Ia.85.5c).

The framing of propositions and the construction of inferences involving them are necessary preconditions of the culminating intellective cognition Aquinas recognizes as *scientia*, which he discusses in greatest detail in his *Sententia super Posteriora analytica* (Commentary on Aristotle's *Posterior Analytics*). The interpretation of his account of *scientia* is controversial, but one helpful way to view it is as follows. To cognize a proposition with *scientia* is, strictly speaking, to accept it as the conclusion of a 'demonstration'. Of course, many premises in demonstrations may themselves be conclusions of other demonstrations; some, however, must be

accepted not on the basis of demonstration but *per se* (*Sententia super Posteriora analytica* I.7.5–8). Such propositions, knowable *per se* (although not always *per se* knowable by us) are Aquinas' first principles. Like Aristotle, he calls them immediate propositions; that is, they cannot themselves be the conclusions of demonstrations, and their truth is evident to anyone who fully understands their terms, who not merely grasps their ordinary meaning but also comprehends the real nature of their referents. The predicate of an immediate proposition belongs to the *ratio* of the proposition's subject, and the *ratio* is the formulation of the subject's real nature (*Sententia super Posteriora analytica* I.10; 33). Thus for example, Aquinas considers 'God exists' to be self-evident, since according to the doctrine of simplicity God's nature is God's existence. 'God exists' is a good example of a proposition knowable *per se* but, as Aquinas insists in rejecting Anselm's ontological argument, not knowable *per se* by us. It is for that reason that he develops a number of *a posteriori* arguments for God's existence, among which the most famous are the 'Five Ways', found in *Summa theologiae* Ia.2.3c (see God, arguments for the existence of).

Anyone who has a developed concept of the subject's real nature is certain of the truth of such an immediate proposition, 'but there are some immediate propositions the terms of which not everyone knows. That is why although the predicate of such a proposition does belong to the ratio of its subject, the proposition need not be granted by everyone, just because its subject's [metaphysical] definition is not known to everyone' (*Sententia super Posteriora analytica* I.5.7). Because proper demonstrations are isomorphic with metaphysical reality, the facts expressed in their premises are regularly to be construed as causes of the facts in their conclusions (*Sententia super Posteriora analytica* I.2.9), although in some cases demonstrative reasoning goes the other way, from effects to causes. So, having *scientia* with respect to some proposition is the fullest possible human cognition, by which one situates the fact expressed by a conclusion in an explanatory theory that accurately maps metaphysical or physical reality.

According to Aquinas, then, what demonstration provides is not so much knowledge as it has been conceived of by foundationalists (for example, Descartes) as depth of understanding and explanatory insight. In general, Aquinas does not begin with self-evident principles and derive conclusions from them deductively; 'rather [he begins] with a statement to be justified (it will become the "conclusion" only in a formal restatement of the argument) and "reduce[s]" it back to its ultimate explanatory principles' (see Durbin, *St Thomas Aquinas* 1968: 82). When Aquinas himself describes his project generally, he says that there are two different processes in which human reason engages: *discovery* (or invention) and *judgment*. When we engage in discovery, we proceed from first principles, reasoning from them to other things; in judgment we reason to first principles on the basis of a kind of analysis. In his view, it is judgment's reasoning process, not that of discovery, that leads to *scientia*, and judgment is the subject of the *Posterior Analytics*: 'Judgment goes with the certitude of *scientia*. And it is because we cannot have certain judgment about effects except by analysis leading to first principles that this part of human reasoning is called "analytics"' (*Sententia super Posteriora analytica*, prooemium).

Sceptical worries seldom intrude on Aquinas' scattered development of his systematically unified theory of knowledge, largely because it is based on a metaphysics in which the first principle of existence is an omniscient, omnipotent, perfectly good God, whose rational creatures could not have been made so as to be standardly mistaken about the rest of creation (see God, concepts of; Knowledge, concept of).

12 Will and action

Philosophy of mind is obviously relevant to epistemology in its account of the mechanisms of cognition, especially of intellect. In its account of will it is just as obviously relevant to action theory and to ethics. Aquinas' concern with moral issues is even greater than his considerable interest in epistemological issues, and his ethics is so fully developed that he integrates his systematic treatment of acts of will into it rather than including such a treatment in his philosophy of mind.

As intellect is the cognitive faculty of the distinctively human rational soul, so will is its appetitive faculty. Will's metaphysical provenance is more primitive than that of intellect; it is merely the most subtle terrestrial instantiation of an utterly universal aspect of creation. Not only every sort of soul but absolutely every form, Aquinas maintains, has some sort of inclination essentially associated with it; and so every hylomorphic thing, even if inanimate, has at least one natural inclination: 'on the basis of its form, fire, for instance, is inclined toward a higher place, and toward generating its like' (*Summa theologiae* Ia.80.1c). Inclination is the genus of appetite, and appetite is the genus of will. The human soul of course involves *natural appetites* – for example, for food – but its sensory and intellective modes of cognition bring with them *sensory appetites*, or passions – for example, for

seafood – and *rational appetite*, or volition – for example, for food low in fat content.

In human beings, sensory appetite, or 'sensuality', is a cluster of inclinations (passions) to which we are subject (passive) by animal nature. Following an Aristotelian line, Aquinas thinks of sensuality as sorted into two complementary powers: the *concupiscible* – pursuit/avoidance instincts – and the *irascible* – competition/aggression/defense instincts. With the former are associated the emotions of joy and sadness, love and hate, desire and repugnance; with the latter, daring and fear, hope and despair, anger.

For philosophy of mind and for ethics, one important issue is the manner and extent of the rational faculties' control of sensuality, a control without which the harmony of the human soul is threatened and morality is impossible – especially in Aquinas' reason-centred ethics with its focus on virtues and vices. A human being who is not aberrantly behaving like a non-rational animal 'is not immediately moved in accordance with the irascible and concupiscible appetite but waits for the command of will, which is the higher appetite' (*Summa theologiae* Ia.81.3c). But the kind of control exercised by a cognitive rational faculty (standardly identified in this role as 'practical reason' rather than the broader 'intellect') is less obvious, and is particularly interesting in view of Aquinas' account of intellective cognition. The rational faculties can direct the attention of the external senses and compensate to some extent for their malfunctioning, but they cannot directly control what the external senses initially perceive on any occasion. On the other hand, sensuality and the internal senses are not directly related to mind-independent external things, and so to some extent 'they are subject to reason's command', although they too can fight against reason (*Summa theologiae* Ia.81.3, ad 3). Elaborating an Aristotelian theme (*Politics* I, 2), Aquinas observes that the soul's rule over the body is 'despotic': in a normal body, any bodily part that can be moved by an act of will will be moved immediately when and as will commands. But the rational faculties rule sensuality 'politically', because the powers and passions that are the intended subjects of this rational governance are also moved by imagination and sense, and so are no slaves to reason. 'That is why we experience the irascible or the concupiscible fighting against reason when we sense or imagine something pleasant that reason forbids, or something unpleasant that reason commands' (*Summa theologiae* Ia.81.3, ad 2).

According to Aquinas, the volition for happiness in general is an ineluctable part of human nature (see §13 below). Nonetheless, 'the movement of a creature's will is not determined in particular to seeking happiness in this, or in that' (*Quaestiones disputatae de veritate* 24.7, ad 6). This sort of freedom of will is freedom of specification or 'freedom as regards the object', freedom in the 'determining' aspect of volition. It is distinguished from freedom of exercise or 'freedom as regards the act', freedom associated with will's 'executive' capacity, for either acting or not acting to achieve something apprehended as good.

The interpretation of Aquinas' account of freedom of will is controversial. The very phrase 'freedom of will' is part of the difficulty, because it imports a concept from a later tradition. Aquinas conceives of freedom as *liberum arbitrium* (free decision or judgment), which cannot be attributed to will alone. It is a property that inheres in the system of intellect and will as a whole, that emerges from their interaction. However, it is perhaps safe to say that, since Aquinas emphatically denies that any volition caused by something extrinsic to the agent can be free, his account of freedom of will is not a version of compatibilism (see for example *Summa theologiae* IaIIae.6.4). The one apparent exception has to do with God's acting on a human will. Aquinas holds that among extrinsic forces, God alone can act directly on some other person's will without violating the will's nature, that is, without undermining its freedom (see for example *Summa theologiae* IaIIae.9.6). On this basis, some interpreters characterize Aquinas as a theological compatibilist; however, the subtle complexities of his account of God's action on human wills leads others to claim that a full appreciation of those complexities would show that Aquinas is not in any sense a compatibilist (see DETERMINISM AND INDETERMINISM; FREE WILL).

Aquinas' analysis of human action, built on his account of will and intellect, is complicated and not readily summarized. Generally speaking, he finds elaborately ordered mental components in even simple acts. For instance, in a case of raising one's hand to attract attention we are likely to suppose that the mental antecedents of the bodily movement are just the agent's combined beliefs and desires, whether or not the agent is fully conscious of them. Aquinas would of course agree that the agent need not be completely aware of the overt action's mental antecedents, but he sees them as having a complex, hierarchical structure.

On his analysis, the action begins when (I1) the agent's intellect apprehends a certain end – attracting attention – as a good to be achieved in these particular circumstances. (I1) thus gives rise to a second component: (W1) the agent's will forms a simple volition for that end. Then, (I2) the agent's intellect considers whether the end can be achieved at that time. If the result of (I2) is affirmative, then

on that basis (W2) the agent's will forms an intention to achieve the end by some means or other. Next, (I3) the agent's intellect surveys the available means and settles on one or more that would be suitable to achieve the end and acceptable to the agent, and (W3) the agent's will accepts the means. If intellect has found more than one suitable and acceptable means, then (I4) intellect compares them and determines which is best in the circumstances, and (W4) will opts for that means. The process comes to its natural end when (W5) the agent's will exercises its control over the agent's arm, and the arm goes up. This ordered series looks deterministic, but as Aquinas views the interaction between intellect and will, the process could go otherwise at almost any point because will could direct intellect to reconsider, to direct attention in some other way, or even just to stop thinking about the issue (*Summa theologiae* IaIIae.6–17).

13 Ethics, law and politics

Aquinas' moral theory is developed most extensively and systematically in the Second Part of *Summa theologiae*. (Broadly speaking, the general theory is in IaIIae and the detailed consideration of particular issues is in IIaIIae.) Like almost all his predecessors, medieval and ancient, Aquinas sees ethics as having two principal topics: first, the ultimate goal of human existence, and second, how that goal is to be won, or lost. Of the 303 Questions making up *Summa theologiae*'s Second Part, 298 are concerned in one way or another with the second topic, and only the first 5 are concerned directly with the first (although in *Summa contra gentiles* III he devotes chapters 25–40 to a detailed examination of it).

Summa theologiae IaIIae.1–5, sometimes called the Treatise on Happiness, develops an argument to establish the existence and nature of a single ultimate end for all human action, or, more strictly, the kind of behaviour over which a person has 'control'. First, 'all actions that proceed from a power are caused by that power in accordance with the nature of its object. But the object of will is an end and a good', that is, an end perceived as good by the willer's intellect (*Summa theologiae* IaIIae.1.1c). From this starting point Aquinas develops an argument designed to show that a human being necessarily (though not always consciously) seeks everything it seeks for its own ultimate end, happiness.

Aquinas argues that the often unrecognized genuine ultimate end for which human beings exist (their 'object') is God, perfect goodness personified; and perfect happiness, the ultimate end with which they may exist (their 'use' of that object), is the enjoyment of the end for which they exist. That enjoyment is fully achieved only in the beatific vision, which Aquinas conceives of as an activity. Since the beatific vision involves the contemplation of the ultimate (first) cause of everything, it is, whatever else it may be, also the perfection of all knowledge and understanding (*Summa theologiae* IaIIae.1.8; 3.8).

Aquinas devotes just four questions of *Summa theologiae* IaIIae (18–21) to 'the goodness and badness of human acts in general'. Although considerations of rightness and wrongness occupy only a little more than ten per cent of the discussion in Questions 18–21, Aquinas nonetheless appears to think of rightness and wrongness as the practical, distinctively moral evaluations of actions. His emphasis on the broader notions of goodness and badness reveals the root of his moral evaluation of actions in his metaphysical identification of being and goodness (see §9 above).

What makes an action morally bad is its moving the agent not toward, but away from, the agent's ultimate goal. Such a deviation is patently irrational, and Aquinas' analysis of the moral badness of human action identifies it as fundamentally irrationality, since irrationality is an obstacle to the actualization of a human being's specifying potentialities, those that make *rational* the differentia of the human species. In this as in every other respect, Aquinas' ethics is reason-centred:

> In connection with human acts the words 'good' and 'bad' are applied on the basis of a comparison to reason, because … a human being's good is existing in accordance with reason, while what is bad for a human being is whatever is contrary to reason. For what is good for any thing is what goes together with it in keeping with its form, and what is bad for it is whatever is contrary to the order associated with its form.
>
> (*Summa theologiae* IaIIae.18.5c)

It would be a mistake, however, to suppose that Aquinas takes moral evil to consist in intellective error. Because of the very close relationship he sees between intellect and will, the irrationality of moral wrongdoing will be a function of will as well, not just of intellect. In Aquinas' view, the moral evaluation of a human action attaches primarily to the 'internal act', the volition from which the external act derives. Since 'will is inclined toward reason's good [the good presented to will by intellect] by the very nature of the power of will', bad volition stems from defective deliberation (*Summa theologiae* IaIIae.50.5, ad 3). As intellect and will continually influence each other, so bad deliberation can also be an effect of bad volition.

Moreover, practical intellect's mistakes in identifying the best available course of action may also have the passions of the sensory soul as sources.

Furthermore, 'because the good [presented by intellect] is varied in many ways, it is necessary that will be inclined through some habit toward some determinate good presented by reason so that [will's determining] activity may follow more promptly' (*Summa theologiae* IaIIae.50.5, ad 3). Habits of will are conditions necessary for our carrying out our volitions in particularly good or particularly bad ways, as regards both the 'executive' and the 'determining' aspects of volition; and the habits that play these crucial roles in Aquinas' moral theory are the virtues and the vices.

The four 'cardinal virtues' can be understood as habits of this sort. Reason's habit of good governance generally is *prudence*; reason's restraint of self-serving concupiscence is *temperance*; reason's persevering despite self-serving 'irascible' passions such as fear is *courage*; reason's governance of one's relations with others despite one's tendencies toward selfishness is *justice*. Aquinas' normative ethics is based not on rules but on virtues; it is concerned with dispositions first and only then with actions. In addition to the moral virtues in all their various manifestations, Aquinas also recognizes intellectual virtues that, like the moral virtues, can be acquired by human effort. On the other hand, the supreme theological virtues of faith, hope and charity cannot be acquired but must be directly 'infused' by God. Aquinas introduces these virtues and others in *Summa theologiae* IaIIae (49–88) and examines them in detail throughout IIaIIae (see VIRTUE ETHICS).

Passions, virtues and vices are all intrinsic principles, or sources, of human acts. However, there are extrinsic principles as well, among which is law in all its varieties. Consequently, Aquinas moves on in *Summa theologiae* IaIIae.90–108 to his Treatise on Law, a famous and original treatment of the subject. The best-known feature of the treatise is Aquinas' concept of natural law. Law in general is 'a kind of rational ordering for the common good, promulgated by the one who takes care of the community' (*Summa theologiae* IaIIae.90.4c), and 'the precepts of natural law are to practical reasoning what the first principles of demonstrations are to theoretical reasoning . . . . All things to be done or to be avoided pertain to the precepts of natural law, which practical reasoning apprehends naturally as being human goods' (IaIIae.94.2c). Human laws of all kinds derive, or should derive, from natural law, which might be construed as the naturally knowable rational principles underlying morality in general: 'From the precepts of natural law, as from general, indemonstrable principles, it is necessary that human reason proceed to making more particular arrangements . . . [which] are called human laws, *provided that* they pertain to the definition (*rationem*) of law already stated' (IaIIae.91.3c). As a consequence of this hierarchy of laws, Aquinas unhesitatingly rejects some kinds and some particular instances of human law, for example: 'A tyrannical law, since it is not in accord with reason, is not unconditionally a law but is, rather, a perversion of law' (IaIIae.92.1, ad 4). Even natural law rests on the more fundamental 'eternal law', which Aquinas identifies as divine providence, 'the very nature of the governance of things on the part of God as ruler of the universe' (IaIIae.91.1c) (see NATURAL LAW).

In *De regimine principum* (The Governance of Rulers), his most important political work, Aquinas begins by sounding the familiar medieval theme: monarchy is the best form of government. However, he realizes that a single ruler is easily corrupted and that monarchy therefore has a tendency to turn into tyranny. He seems not to countenance revolution against a legitimate ruler who has become tyrannical (*De regimine principium* 6), but he maintains that radical means, including tyrannicide, may be justified against a usurper. Perhaps because he came to appreciate the dangers in monarchy, he gradually works republican elements into his theory of good government. His later commentary on Aristotle's *Politics* seems to erode the dominant monarchical model further in its treatment of the notions of the commonwealth (*res publica*) and of the citizen as one who rules and is ruled in turn (see POLITICAL PHILOSOPHY, HISTORY OF).

14 Theology: natural, revealed and philosophical

Because Aquinas developed most of his thought within the formal confines of thirteenth-century theology, and because this has in turn affected his place in the history of philosophy and the assessment of his work, some attention must be paid to the ways in which much of what we recognize as philosophy was an essential component of what he thought of as theology.

Aquinas devotes the first three books of *Summa contra gentiles* to a systematic development of natural theology, which he saw as part of philosophy (*Summa theologiae* Ia.1.1, ad 2) (see NATURAL THEOLOGY). As part of philosophy, natural theology must of course be based entirely on 'principles known by the natural light of intellect' (*Summa theologiae* Ia.1.2c), principles of the sort that underlie Aristotle's metaphysics, which Aristotle himself thought of as culminating in 'theology' (see Aquinas' interpretation of that thought in the prooemium to his *Sententia super Metaphysicam*

(Commentary on Aristotle's *Metaphysics*). In fact, the way Aquinas works in *Summa contra gentiles* I–III strongly suggests that he may have thought of natural theology as a science subordinate to metaphysics, somewhat as he would have understood optics to be subordinate to geometry.

However, there is something odd about that project of his. By Aquinas' day the churchmen governing universities had overcome most of their initial misgivings about the recently recovered works of the pagan Aristotle, and had acknowledged officially that the study of Aristotelian physics and metaphysics (with their integrated minor component of natural theology) was compatible with the then universally recognized availability of revealed truths about God. Medieval Christians had come to appreciate the ancient philosophers' attempts to uncover truths about God on the basis of observation and reasoning alone as having been justified, even commendable, given their total ignorance of revelation. However, no philosopher in Aquinas' circumstances could have justifiably undertaken a new project of natural theology heuristically.

Still, no opprobrium would attach to natural theology taken up expositionally. The aim of such an enterprise would be not to develop theology from scratch but rather to show, in the spirit of Romans 1: 20, the extent to which what had been supernaturally revealed could, in theory, have been naturally discovered. Such an enterprise is what *Summa contra gentiles* I–III seems to represent.

Evidence from a chronicle written about seventy years after Aquinas began *Summa contra gentiles* once led scholars to suppose that he had written it as a manual for the use of Dominican missionaries to Muslims and Jews. If that were so, then the work's presentation of natural instead of revealed theology in its first three books would have been dictated by the practical purpose of rationally deriving the truth about God, and about God's relation to everything else, for people who would not have acknowledged the revealed texts Aquinas would otherwise have cited as the source of that truth. But nobody, and certainly not Aquinas, could have supposed that Muslims or Jews needed to be argued into perfect-being monotheism of the sort developed in those first three books, which contain nothing that he would have taken to be contrary to Judaism or Islam. If Aquinas had intended *Summa contra gentiles* as a manual for missionaries to educated Muslims, Jews or Christian heretics, he would have wasted the enormous effort represented in the 366 copiously argued chapters of Books I–III.

What Aquinas himself says about his purpose in writing *Summa contra gentiles* suggests that what he wrote had at least its formal cause not in an attempt to aid missionary activities, but instead in his consideration of the interrelation of philosophy and Christianity. He begins by writing about the concerns of a wise person, one of those 'who give things an appropriate order and direction and govern them well' (*Summa contra gentiles* I.1.2). Obviously, such a person has to be concerned with goals and sources, and so the wisest person will be 'one whose attention is turned toward the universal goal, which is also the universal source', which Aquinas takes to be God (I.1.3). Because this natural theology is oriented as it is, 'it must be called the greatest wisdom itself, as considering the absolutely highest cause of all' (II.4.874). Therefore, the highest, most universal explanatory truth must be wisdom's concern. Anyone aspiring to wisdom will attend to metaphysics, since, Aquinas reports, Aristotle rightly identified metaphysics as 'the science of truth – not of just any truth, but of the truth that is the origin of all truth, the truth that pertains to the first principle of being for all things' (I.1.5). And, as he says in an observation that suits his own enterprise, 'sometimes divine wisdom proceeds from human philosophy's starting points' (II.4.875). However, since it is the business of one and the same science 'to pursue one of two contraries and to repel the other ... the role of the wise person is to meditate on the truth, especially the truth regarding the first principle, and to discuss it with others, but also to fight against the falsity that is its contrary' (I.1.6). The truth regarding the first principle will be the truth about God, supposing natural theology can show that God exists; and so the explanatory truth associated here with metaphysics is the truth associated also with theology.

No one knows what title, if any, Aquinas himself gave to this work. In some of its medieval manuscripts, it is entitled *Liber de veritate catholicae fidei contra errores* (A Book About the Truth of the Catholic Faith, Directed Against Mistakes), a title that comes closer to accurately representing the book's aim and contents than the more pugnacious, traditional *Summa contra gentiles* (Synopsis [of Christian Doctrine] Directed Against Unbelievers). During the nineteenth century, when *Summa theologiae* (Synopsis of Theology) was instead normally referred to as *Summa theologica* (Theological Synopsis), *Summa contra gentiles* was sometimes published under the deliberately contrasting title *Summa philosophica* (Philosophical Synopsis). That contrast, although potentially misleading, has some truth in it, as may be seen in Aquinas' plan for *Summa contra gentiles* I–III: 'Since we intend to pursue by way of reason the things about God that human reason can investigate, the first consideration is of matters associated with God considered in himself [Book I]; second, of the emergence of created things from him [Book II]; third, of the

ordering and directing of created things toward him as their goal [Book III]' (I.9.57).

In this pursuit by way of reason, Aquinas must and does shun 'authoritative arguments' of any sort, but he shows good sense in not restricting himself to 'demonstrative arguments' in developing natural theology. He does, of course, use demonstrative arguments when he thinks he has them, but, like almost all philosophers of any period, he recognizes philosophy's need for 'probable aguments' as well. A demonstrative argument takes as its premises propositions that explain the fact in the argument's conclusion by elucidating its causes (or, sometimes, its effects), and so it produces, or presents, scientific understanding. A probable argument – the sort that has always been most prevalent and most appropriate in philosophy – is one based on premises of any sort that are accepted widely or by experts in the relevant field, and so one group may be convinced by a probable argument that another group rejects. Of course, Aquinas has to make use of authoritative arguments in the fourth (and last) book, where he turns from natural to revealed theology, and his tolerance of them there is part of what distinguishes Book IV's argumentation from the sort that characterizes Books I–III.

In *Summa contra gentiles* IV, Aquinas engages in what has come to be called *philosophical theology*, the application of reason to revelation. Philosophical theology shares the methods of natural theology broadly conceived – in other words, analysis and argumentation of all the sorts accepted in philosophy – but it lifts natural theology's restriction on premises, accepting as assumptions revealed propositions. This includes those that are initially inaccessible to unaided reason, such as the 'mysteries' of Christian doctrine. In his many works of philosophical theology, Aquinas tests the coherence of doctrinal propositions (including the mysteries), attempts explanations of them, uncovers their logical connections with other doctrinal propositions and so on, in order to bear out his conviction that the doctrines themselves are eminently understandable and acceptable, and that the apparent incoherence of some of them is only a feature of our initial, superficial view of them.

Summa theologiae is the paradigm of philosophical theology. The very first Article of the very first Question makes it clear at once that it is not natural theology that *Summa theologiae* is a summa of, since it begins by asking whether we need any 'other teaching, besides philosophical studies'; which in Aquinas' usage means the studies that medieval beginners in theology would have just completed in the arts faculty. The question arises because philosophical studies are characterized not only as dealing with 'the things that are subject to reason', but also as encompassing 'all beings, including God', as a consequence of which 'part of philosophy is called theology'.

Although Aquinas accepts this characterization of philosophy's subject matter as universal and as including a part that is properly called theology, he offers several arguments to support his claim that revealed theology is nonetheless not superfluous. In one of those arguments, he claims that a thing's 'capacity for being cognized in various ways brings about a difference between sciences'. By this he means that different sciences can reason to some of the same conclusions on the basis of different premises or evidence. In his example, he points out that in order to support the proposition that the earth is round a naturalist uses empirical observations, while a cosmologist might support that same conclusion on a strictly formal basis. 'And for that reason', he concludes, 'nothing prevents the same things from being treated by philosophical studies insofar as they can be cognized by the light of natural reason, and also by another science insofar as they are cognized by the light of divine revelation. That is why the theology that pertains to *sacra doctrina* [in other words, revealed theology] differs in kind from the theology that is considered a part of philosophy' (ad 2).

In this argument, Aquinas might appear willing to concede that revealed and natural theology differ only in this methodological respect, that they simply constitute two radically different ways of approaching the very same propositions about God and everything else. However, he would not actually concede this. There are propositions that belong uniquely to revealed theology's subject matter, simply because the different premises with which revealed theology begins can also lead to conclusions not available to unaided reason. And, of course, no doctrinal proposition that is initially available to human beings only in virtue of having been revealed by God can be part of natural theology's subject matter.

On the other hand, no propositions appropriate to natural theology are excluded from *Summa theologiae*'s subject matter. The propositions that belong to natural theology form a proper subset of those that belong to revealed theology:

> It was necessary that human beings be instructed by divine revelation even as regards the things about God that human reason can explore. For the truth about God investigated by a few on the basis of reason [without relying on revelation] would emerge for people [only] after a long time and tainted with many mistakes. And yet all human well-being, which has to do with God, depends on

> the cognition of that truth. Therefore, it was necessary for human beings to be instructed about divine matters through divine revelation so that [the nature of human] well-being might emerge for people more conveniently and with greater certainty.
>
> (*Summa theologiae* Ia.1.1c)

When he sums up his examination of *sacra doctrina*, or revealed theology, Aquinas says that its 'main aim . . . is to transmit a cognition of God, and not only as he is in himself, but also as he is the source of things, and their goal – especially of the rational creature' (*Summa theologiae* Ia.2, intro.). Thus the subject matter of *sacra doctrina*, the theology presented in this summa of theology, is the most basic truths about *everything*, with two provisos: first, it is about God and about things other than God as they relate to God as their source and goal; second, among things other than God it deals with, it is especially about human beings, whose study of theology should be motivated by the fact that their wellbeing depends specially on their grasp of certain theological truths. And, Aquinas insists, universal scope is just what one should expect in a rational investigation of the truth about God: 'All things are considered in *sacra doctrina* under the concept of God, either because they *are* God, or because they have an ordered relationship *to* God as to their source and goal. It follows from this that the subject of this science is really God', even though the intended explanatory scope of the science is universal (*Summa theologiae* Ia.1.7c).

In referring to *sacra doctrina* as a 'science', Aquinas means to characterize it as a systematic, reasoned presentation of an organized body of knowledge consisting of general truths about some reasonably unified subject matter. In that broadly Aristotelian sense, it is not obviously wrong to think of theology as a science (as it would be in the narrower, twentieth-century sense of 'science'). It is in that sense that the science of theology as Aquinas develops it in *Summa theologiae* would now be called philosophical theology, the enterprise of employing the techniques and devices of philosophy in clarifying, supporting and extending the propositions that are supposed to have been revealed for theology's starting points. Thus, some of the work of philosophical theology is an attempt to explain revealed propositions and systematically work out their implications.

Like natural theology, which is subordinate to metaphysics, philosophical theology is a subordinate science. However, because it begins its work on divinely revealed propositions, Aquinas identifies the 'science' to which it is subordinate as God's knowledge of himself and everything else, available to human beings directly only in the afterlife (*Summa theologiae* Ia.1.2c). As he says earlier, 'For us, the goal of faith is to arrive at an understanding of what we believe – [which is] as if a practitioner of a subordinate science were to acquire in addition the knowledge possessed by a practitioner of the higher science. In that case the things that were only believed before would come to be known, or understood' (*Expositio super librum Boethii de trinitate* 2.2, ad 7).

Not even the doctrinal mysteries are impervious to rational investigation, although unaided reason could never have discovered them. Regarding one central mystery, for example, Aquinas says: 'It is impossible to arrive at a cognition of the Trinity of the divine persons by means of natural reason' (*Summa theologiae* Ia.32.1c). However, he says this in the twenty-second of a series of seventy-seven articles of *Summa theologiae* devoted to analysing and arguing about the details of Trinity; in other words, in the midst of subjecting this mystery to philosophical theology. As he explains in the very Article in which he rules out the possibility of rationally discovering that there are three divine persons:

> There are two ways in which reason is employed regarding any matter . . . in one way to provide sufficient proof of something fundamental . . . in the other way to show that consequent effects are suited to something fundamental that has already been posited . . . . It is in the first way, then, that reason can be employed to prove that God is one, and things of that sort. But it is in the second way that reason is employed in a clarification of Trinity. For once Trinity has been posited, reasonings of that sort are suitable, although not so as to provide a sufficient proof of the Trinity of persons by those reasonings.
>
> (*Summa theologiae* Ia.32.1c)

Aquinas is also careful to point out that it isn't mere intellectual curiosity or even a defense of the faith that is served by a rational clarification of Trinity. In his view, this application of philosophical theology – confirming faith by reason, showing that Trinity is not after all irrational, exposing the intricate connections between these and other doctrinal propositions – aids one's understanding of creation and salvation (see TRINITY).

ARCHĒ

Archē, or 'principle', is an ancient Greek philosophical term. Building on earlier uses, Aristotle established it as a technical term with a number of related meanings, including 'originating source', 'cause', 'principle of knowledge' and 'basic entity'. Accordingly, it acquired importance in metaphysics, epistemology and philosophy of science, and also in the particular sciences. According to Aristotle's doctrine of scientific principles, all sciences and all scientific knowledge are founded on principles (*archai*) of a limited number of determinate kinds.

ARCHITECTURE, AESTHETICS OF

The philosophy of architecture is a branch of philosophical aesthetics concerned with various issues arising from the theory and practice of building design. The oldest writings on architecture date from antiquity and link architectural principles to more general, metaphysical elements of form and order. This tradition persisted into and beyond the Renaissance, but in the eighteenth century it began to give way to new philosophies of mind and value, according to which the determining factors of aesthetic experience are the interests and attitudes of informed subjects. Thereby architecture came within the sphere of the theory of taste.

Nineteenth-century revivals of classical and Gothic styles produced renewed interest in the nature of architecture, its place within the scheme of arts and sciences, and its role in society. Following this, twentieth-century modernism offered various accounts of the rational basis of architectural form and combined these with utopian political philosophies. As it had been in antiquity and during the Renaissance, architecture was again viewed as central to and partly definitive of a culture. More recently, however, attention has returned to analytical questions such as 'What is the nature of the aesthetic experience of architecture?' and, relatedly, 'How is it possible for there to be reasoned, critical judgments about the meaning and value of buildings?'

In order to deal with such issues philosophers in different traditions have begun to develop accounts of the social aspects of architecture, recognizing that critical judgments presuppose the capacity to identify buildings as being of various types: public, domestic, formal, informal and so on. The nature of architecture is in part, therefore, a matter of social convention or more generally 'forms of life', and this limits the scope for abstract ahistorical theorizing. None the less, the resources of metaphysics, the theories of mind, action, meaning and value are all utilized in contemporary philosophy of architecture.

JOHN J. HALDANE

ARENDT, HANNAH (1906–75)

Hannah Arendt was one of the leading political thinkers of the twentieth century. She observed Nazi totalitarianism at close quarters and devoted much of her life to making sense of it. In her view it mobilized the atomized masses around a simple-minded ideology, and devised a form of rule in which bureaucratically minded officials performed murderous deeds with a clear conscience. For Arendt the only way to avoid totalitarianism was to establish a well-ordered political community that encouraged public participation and institutionalized political freedom. She considered politics to be one of the highest human activities because it enabled citizens to reflect on their collective life, to give meaning to their personal lives and to develop a creative and cohesive community. She was deeply worried that the economically obsessed modern age discouraged political activity, and created morally superficial people susceptible to the appeal of mindless adventurism.

B. PAREKH

ARETĒ

A pivotal term of ancient Greek ethics, *aretē* is conventionally translated as 'virtue', but is more properly 'goodness' – the quality of being a good human being. Philosophy came, largely through Plato, to recognize four cardinal *aretai*: wisdom (*phronēsis*), moderation (*sōphrosynē*), courage (*andreia*)

and justice (*dikaiosynē*). Others, considered either coordinate with these or their sub-species, included piety, liberality and magnanimity. The term generated many controversies. For example, is *aretē* a state of intellect, character or both? Does it possess intrinsic or only instrumental value? Is it teachable, god-given or otherwise acquired? Is it one thing or many? If many, how are they differentiated, and can you have one without having all?

DAVID SEDLEY

ARISTOTLE (384–322 BC)

Introduction

Aristotle of Stagira is one of the two most important philosophers of the ancient world, and one of the four or five most important of any time or place. He was not an Athenian, but he spent most of his life as a student and teacher of philosophy in Athens. For twenty years he was a member of Plato's Academy; later he set up his own philosophical school, the Lyceum. During his lifetime he published philosophical dialogues, of which only fragments now survive. The 'Aristotelian corpus' (1,462 pages of Greek text, including some spurious works) is probably derived from the lectures that he gave in the Lyceum.

Aristotle is the founder not only of philosophy as a discipline with distinct areas or branches, but, still more generally, of the conception of intellectual inquiry as falling into distinct disciplines. He insists, for instance, that the standards of proof and evidence for deductive logic and mathematics should not be applied to the study of nature, and that neither of these disciplines should be taken as a proper model for moral and political inquiry. He distinguishes philosophical reflection on a discipline from the practice of the discipline itself. The corpus contains contributions to many different disciplines, not only to philosophy.

Some areas of inquiry in which Aristotle makes a fundamental contribution are as follows:

(1) Logic. Aristotle's *Prior Analytics* constitutes the first attempt to formulate a system of deductive formal logic, based on the theory of the 'syllogism'. The *Posterior Analytics* uses this system to formulate an account of rigorous scientific knowledge. 'Logic', as Aristotle conceives it, also includes the study of language, meaning and their relation to non-linguistic reality; hence it includes many topics that might now be assigned to philosophy of language or philosophical logic (*Categories*, *De Interpretatione*, *Topics*).

(2) The study of nature. About a quarter of the corpus (see especially the *History of Animals*, *Parts of Animals*, and *Generation of Animals*; also *Movement of Animals*, *Progression of Animals*) consists of works concerned with biology. Some of these contain collections of detailed observations. (The *Meteorology* contains a similar collection on inanimate nature.) Others try to explain these observations in the light of the explanatory scheme that Aristotle defends in his more theoretical reflections on the study of nature. These reflections (especially in the *Physics* and in *Generation and Corruption*) develop an account of nature, form, matter, cause and change that expresses Aristotle's views about the understanding and explanation of natural organisms and their behaviour. Natural philosophy and cosmology are combined in *On the Heavens*.

(3) Metaphysics. In his reflections on the foundations and presuppositions of other disciplines, Aristotle describes a universal 'science of being *qua* being', the concern of the *Metaphysics*. Part of this universal science examines the foundations of inquiry into nature. Aristotle formulates his doctrine of substance, which he explains through the connected contrasts between form and matter, and between potentiality and actuality. One of his aims is to describe the distinctive and irreducible character of living organisms. Another aim of the universal science is to use his examination of substance to give an account of divine substance, the ultimate principle of the cosmic order.

(4) Philosophy of mind. The doctrine of form and matter is used to explain the relation of soul and body, and the different types of soul found in different types of living creatures. In Aristotle's view, the soul is the form of a living body. He examines the different aspects of this form in plants, non-rational animals and human beings, by describing nutrition, perception, thought and desire. His discussion (in *On the Soul*, and also in the *Parva Naturalia*) ranges over topics in philosophy of mind, psychology, physiology, epistemology and theory of action.

(5) Ethics and politics (*Nicomachean Ethics*, *Eudemian Ethics*, *Magna Moralia*). In Aristotle's view, the understanding of the natural and essential aims of human agents is the right basis for a grasp of principles guiding moral and political practice. These principles are expressed in his account of human wellbeing, and of the different virtues that constitute a good person and promote wellbeing. The description of a society that embodies these virtues in individual and social life is a task for the *Politics*, which also examines the virtues and vices of

actual states and societies, measuring them against the principles derived from ethical theory.

(6) Literary criticism and rhetorical theory (*Poetics*, *Rhetoric*). These works are closely connected both to Aristotle's logic and to his ethical and political theory.

1 Life

Aristotle was born in 384 BC, in the Macedonian city of Stagira, now part of northern Greece. In his lifetime the kingdom of Macedon, first under Philip and then under Philip's son Alexander ('the Great'), conquered both the Greek cities of Europe and Asia and the Persian Empire. Although Aristotle spent much of his adult life in Athens, he was not an Athenian citizen. He was closely linked to the kings of Macedon, whom many Greeks regarded as foreign invaders; hence, he was affected by the volatile relations between Macedon and the Greek cities, especially Athens.

Aristotle was the son of Nicomachus, a doctor attached to the Macedonian court. In 367 BC Aristotle came to Athens. He belonged to Plato's Academy until the death of Plato in 347; during these years Plato wrote his important later dialogues (including the *Sophist*, *Timaeus*, *Philebus*, *Statesman*, and *Laws*), which reconsider many of the doctrines of his earlier dialogues and pursue new lines of thought. Since there was no dogmatic system of 'Platonism', Aristotle was neither a disciple of such a system nor a rebel against it. The exploratory and critical outlook of the Academy probably encouraged Aristotle's own philosophical growth.

In 347 BC Aristotle left Athens, for Assos in Asia Minor. Later he moved to Lesbos, in the eastern Aegean, and then to Macedon, where he was a tutor of Alexander. In 334 he returned to Athens and founded his own school, the Lyceum. In 323 Alexander died; in the resulting outbreak of anti-Macedonian feeling in Athens Aristotle left for Chalcis, on the island of Euboea, where he died in 322.

Aristotle married Pythias, a niece of Hermeias, the ruler of Assos. They had a daughter, also called Pythias. After the death of his wife, Aristotle formed an attachment to Herpyllis, and they had a son Nicomachus.

2 Order of Aristotle's works

By the end of Aristotle's life the Lyceum must have become a well-established school. It lasted after Aristotle's death; his successor as head of the school was his pupil Theophrastus. Many of the works in the Aristotelian corpus appear to be closely related to Aristotle's lectures in the Lyceum. The polished character of some passages suggests preparation for publication (for example, *Parts of Animals* I 5), but many passages contain incomplete sentences and compressed allusions, suggesting notes that a lecturer might expand (for example, *Metaphysics* VII 13). We cannot tell how many of his treatises Aristotle regarded as 'finished' (see §11 on the *Metaphysics* and §21 on the *Ethics*).

It may be wrong, therefore, to ask about the 'date' of a particular treatise. If Aristotle neither published nor intended to publish the treatises, a given treatise may easily contain contributions from different dates. For similar reasons, we cannot plausibly take cross-references from one work to another as evidence of the order of the works. External, biographical considerations are unhelpful, since we lack the evidence to support any detailed intellectual biography of Aristotle.

A few points, however, may suggest a partial chronology.

(1) Some of Aristotle's frequent critical discussions of Plato and other Academics may have been written (in some version) during Aristotle's years in

the Academy. The *Topics* may reflect the character of dialectical debates in the Academy.
(2) It is easier to understand the relation of the doctrine of substance in the *Categories* and *Physics* I–II to the doctrine and argument of *Metaphysics* VII if we suppose that *Metaphysics* VII is later.
(3) The Organon (see §4) does not mention matter, perhaps because (a) Aristotle had not yet thought of it, or because (b) he regarded it as irrelevant to the topics considered in the Organon. If (a) is correct, the Organon precedes the works on natural philosophy.
(4) Some of the observations used in Aristotle's biological works probably came from the eastern Aegean. Hence, Aristotle probably pursued his biological research during his years away from Athens. We might trace his biological interests to the Academy (see Plato's *Timaeus*); he may also have acquired them from his father Nicomachus, who was a doctor. Probably, then, at least some of the biological works (or versions of them) are not the latest works in the corpus.
(5) The *Magna Moralia* (if it is genuine) and the *Eudemian Ethics* probably precede the *Nicomachean Ethics* (see §21).

The order in which Aristotle's works appear in the Greek manuscripts goes back to early editors and commentators (from the first century BC to the sixth century AD); it reflects their view not about the order in which the works were written, but about the order in which they should be studied. This entry generally follows the order of the corpus, except that it discusses *On the Soul* after the *Metaphysics* (see §17), not among the works on natural philosophy (where it appears in the manuscripts).

3 Appearances

The general aim of rational inquiry, according to Aristotle, is to advance from what is 'better known to us' to what is 'better known by nature' (see *Physics* I 1; *Posterior Analytics* 71b33; *Metaphysics* 1029b3). We achieve this aim if: (1) we replace propositions that we thought we knew with propositions that we really know because they are true and we understand them; (2) we find general principles that explain and justify the more specific truths that we began from; (3) we find those aspects of reality that explain the aspects that are more familiar to us.

The things better known to us in a particular area are the relevant 'appearances' (*phainomena*). Aristotle presents them through detailed collections of empirical data, reached as a result of 'inquiry' (*historia*; for example, *Parts of Animals* 646a8). Empirical inquiry proceeds from particular observations, by means of generalizations through induction (*epagōgē*) from these particular cases, until we reach experience (*empeiria*). Experience leads us to principles that are better known by nature (*Prior Analytics* 46a17); we also rely on it to test principles we have found (*Generation of Animals* 760b28).

Philosophical inquiry also relies on 'appearances'. However, the appearances that concern it are not empirical observations, but common beliefs, assumptions widely shared by 'the many and the wise'. The critical and constructive study of these common beliefs is 'dialectic'. Aristotle's method is basically Socratic. He raises puzzles in the common beliefs, looking for an account that will do them justice as a whole. Among common beliefs Aristotle considers the views of his predecessors (for example, *Metaphysics* I; *On the Soul* I; *Politics* II), because the puzzles raised by their views help us to find better solutions than they found.

Inquiry leads us to causes and to universals. Aristotle has a realist conception of inquiry and knowledge; beliefs and theories are true in so far as they grasp the reality that we inquire into (see REALISM AND ANTIREALISM §2). Universals and causes are 'prior by nature'; they are not created by, or dependent on, any theory, but a true theory must fit them.

If we attended only to Aristotle's remarks on what is better known to us and on the process of inquiry, we might regard his position as a form of empiricism (see EMPIRICISM). But in his remarks on what is better known by nature, he insists on the reality of universals and on the importance of non-sensory forms of knowledge (see §15 on universals, §19 on thought).

4 Thought and language

One means of access to appearances, and especially to common beliefs, is the study of what words and sentences 'signify' (*sēmainein*). This is part of 'logic' (*logikē*, derived from *logos*, which may be translated 'word', 'speech', 'statement', 'argument' or 'reason': see LOGOS), which is discussed in the first section of Aristotle's works (*Categories*, *De Interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics*). This section of the corpus came to be called the 'Organon' ('instrument'), because logic, as Aristotle conceives it, concerns statements and arguments in general, without restriction to any specific subject matter; it is therefore an instrument of philosophical inquiry in general, rather than a branch of philosophy coordinate with natural philosophy or ethics. The Organon includes some elements of philosophy of language, as well as formal logic (syllogistic; see §5) and epistemology (see §6).

According to Aristotle's account of signification (see especially *De Interpretatione* 1–4), as commonly

understood, the word 'horse' signifies horse by signifying the thought of horse; in using the word, we communicate thoughts about horses. When the thoughts about horses we communicate are true, we communicate truths about the universal horse; even when our thoughts are not completely true, we may signify the same universal horse.

To understand the signification of a name '*F*', we look for the corresponding definition (*logos*, *horismos*) of *F*. Aristotle distinguishes nominal definitions, stating the beliefs associated with the name, from real definitions, giving a true account of the universal that underlies the beliefs embodied in the nominal definition (see *Posterior Analytics* II 8–10. Aristotle himself does not use the labels 'nominal definition' and 'real definition'.).

Not every name corresponds to one nominal and one real definition. Some names correspond to no genuine universal; 'goatstag' signifies (in one way) animals that are both goats and stags, but it does not signify a genuine universal, since there is no natural kind of goatstag. Other names correspond to more than one universal, as 'chest' signifies both a container and a part of an animal. Chests are 'homonymous' (*homōnyma*) or 'multivocal' (*pollachōs legomena*; 'spoken of in many ways'); more than one definition is needed to capture the signification of the name. By contrast, since only one definition corresponds to the name 'horse', horses are 'synonymous' (*Categories* 1).

Other philosophers make serious errors, Aristotle believes, because they suppose they can give a single account of things or properties that are really multivocal. Once we see that different *F*s are *F* in different ways, we see that different, although (in many cases) connected, accounts of what it is to be *F* must be given. Some philosophically important cases of multivocity are cause (Aristotle's doctrine of the four causes; see §9), being (the doctrine of the categories; see §7) and good (the criticism of Plato's belief in a Form of the Good; *Nicomachean Ethics* I 6).

5 Deduction

Part of logic, as Aristotle conceives it, is the study of good and bad arguments. In the *Topics* Aristotle treats dialectical arguments in general. In the *Prior Analytics* he examines one type of argument, a 'deduction' (*syllogismos*; literally, 'reasoning', hence the standard term 'syllogism'). This is an argument in which, if propositions *p* and *q* are assumed, something else *r*, different from *p* and *q*, follows necessarily because of the truth of *p* and *q* (*Prior Analytics* 24b18–20, paraphrased). Aristotle insists that it is not possible for the premises of a deduction to be true and the conclusion false ('follows necessarily'); that a deduction must have more than one premise ('if *p* and *q* are assumed'); that the conclusion cannot be identical to any premise ('different from *p* and *q*'); and that no redundant premises are allowed ('because of the truth of *p* and *q*'). He takes deductions to express affirmative or negative relations between universals, taken either universally ('Animal belongs to every (no) man') or not universally ('Animal belongs (does not belong) to some man'). He takes the affirmative and negative claims to imply existence (so that 'Biped belongs to some dodo' follows from 'Biped belongs to every dodo'; the latter affirmation is not equivalent, therefore, to 'If anything is a dodo, it is biped').

These different features of an Aristotelian deduction differentiate Aristotle's account of a deduction from a more familiar account of deductively valid arguments. An argument may be valid even if it is redundant, or a premise is identical to the conclusion, or it has only one premise, or it is about particulars, or it contains neither 'some' nor 'every' nor 'belongs'; but no such argument is an Aristotelian deduction. Aristotle's theory of the different forms of deduction (often called 'the moods of the syllogism') examines the various forms of argument that necessarily preserve the truth of their premises. He begins from 'complete' (or 'perfect') deductions whose validity is evident, and classifies the different types of arguments that can be derived from (shown to be equivalent to) the complete deductions. He also explores the logical relations between propositions involving modalities ('Necessarily (possibly) animal belongs to every man' and so on). Since Aristotle accepts this relatively narrow account of a deduction, his exploration of the different forms of deduction is not a theory of valid arguments in general; the Stoics come much closer to offering such a theory (see Stoicism).

Aristotle's theory of deduction is developed for its own sake, but it also has two main philosophical applications. (1) Deduction is one type of argument appropriate to dialectic (and, with modifications, to rhetoric; see §29). Aristotle contrasts it with inductive argument (also used in dialectic), in which the conclusion does not follow necessarily from the premises, but is made plausible by them. (2) It is essential for demonstration (*apodeixis*), which Aristotle takes to be the appropriate form for exhibiting scientific knowledge.

6 Knowledge, science and demonstration

The progress from what is known to us to what is known by nature aims at *epistēmē*, the scientific knowledge whose structure is exhibited in the demonstrative pattern described in the *Posterior*

Analytics. A demonstration is a deduction in which the premises are necessarily true, prior to and better known than the conclusions, and explanatory of the conclusions derived from them. Aristotle assumes that if I know that *p*, then I can cite some justification *q*, to justify my belief that *p*, and I also know why *q* justifies *p* (*Posterior Analytics* I 2). The right sort of justification relies on things better known by nature – the general laws and principles that explain the truth of *p*. Since these are embodied in demonstrations, grasp of a demonstration of *p* expresses knowledge of *p*. Aristotle's theory of demonstration, then, is not intended to describe a procedure of scientific inquiry that begins from appearances; it is an account of the knowledge that is achieved by successful inquiry.

To show that a deduction is a demonstration, we must show that its premises are better known than the conclusion. Sometimes we can show this by demonstrating them from higher premises that are even better known. This process of justification, Aristotle claims, must be linear and finite. A circular 'justification' must eventually 'justify' a given belief by appeal to itself, and an infinite regress imposes on us a task that we can never complete. Since, therefore, neither a circle nor an infinite regress can really justify, a proper justification must ultimately appeal to primary principles of a science.

These primary principles are 'assumptions' (*hypotheseis*); we must see that they are better known and prior to other truths of a science, without being derived from any further principles. Since they are the basis of all demonstration, they cannot themselves be demonstrated; Aristotle claims that we have non-demonstrative understanding (*nous*: *Posterior Analytics* II 19) of the ultimate principles of each science (see NOUS).

How are we entitled to claim understanding of an ultimate principle? Aristotle believes that the principles of a science are reached from appearances (perceptual or dialectical or both), which are the starting points known to us. He may believe that this relation of the principles to appearances justifies us in accepting them as first principles and in claiming to have understanding of them. This explanation, however, does not easily fit Aristotle's demand for linear and finite chains of justification. That demand suggests that the assumptions of a science must be self-evident (seen to be true without any inferential justification), so that his conception of knowledge expresses a foundationalist position (see FOUNDATIONALISM). (On difficulties in foundationalism see AGRIPPA.)

Although Aristotle's aim of reaching a demonstrative science reveals some of his epistemological doctrines and assumptions, it does not evidently influence most of the structure or content of most of the surviving treatises. In his main philosophical works, the influence of dialectical methods and aims is more apparent.

7 Categories and beings

Part of the task of logic is to explain the nature of predication ('*A* is *B*', analysed by Aristotle as '*B* is predicated of *A*' or '*B* belongs to *A*', as in 'Animal belongs to every man'), which is presupposed by complex *logoi* (statements and arguments). In the *Categories* (*katēgoriai*; predications), Aristotle introduces ten 'categories' (usually called *schēmata tēs katēgorias*, 'figures (that is, types) of predication'). The categories correspond to different sorts of words (for example, count-nouns, adjectives, verbs) and to different grammatical functions (for example, subject, predicate), but they primarily classify the different non-linguistic items introduced in predications. The sentences 'Socrates is a man' and 'Socrates is a musician' are grammatically similar, but they introduce different sorts of things; the first predicates a second substance of a first substance, whereas the second predicates a non-substance of a first substance.

The first category is called *ousia* (literally, 'being'), which is translated into Latin as 'substantia', and hence usually called 'substance' (see SUBSTANCE). The nine non-substance categories include quality, quantity and relative (the only ones that Aristotle refers to often; the categories are listed in *Categories* 4, *Topics* I 9). Each category contains both particulars and universals. The statement that this individual man is an animal predicates a second substance (that is, a universal in the category of substance) of a first substance (that is, a particular in the category of substance). 'White is a colour' predicates one universal quality of another.

The categories display the multivocity of beings (see §4). Whereas animals constitute an ordinary univocal genus with a single definition, beings do not constitute an ordinary genus; hence there is no single account of what it is for something to be a being. Aristotle believes Plato mistakenly pursued a single account of beings; the theory of categories is meant to avoid Platonic errors.

In marking categorial divisions, Aristotle is influenced by grammar and syntax, but also by his ontology – his classification of beings. This classification rests on his view of nature and change, which clarifies his analysis of predication.

8 Change and substance

Aristotle's *Physics* discusses nature, *physis*. The nature of *x* is a principle (or 'source'; *archē*), internal to *x*, of change and stability in *x*; hence the inquiry into

nature leads to a discussion of change in natural substances (the elements, plants and animals). Aristotle proceeds dialectically, raising and solving puzzles involved in the understanding of natural change. In solving the puzzles, he introduces the different types of beings that are presupposed by a coherent account of natural change.

In *Physics* I 7–8, Aristotle analyses a simple example of change – Socrates changing from being pale to being tanned. This change involves a subject (or 'underlying thing'; *hypokeimenon*), Socrates, who loses one contrary (his pale colour) and acquires another contrary (his tan). Neither of the contraries persists, but the subject persists (otherwise there would not be a change in Socrates). This particular subject that persists through change is what the *Categories* calls a first substance. First substances differ both from second substances and from non-substances by being capable of undergoing change; they persist while receiving opposites (as Socrates is first pale and then tanned). They cannot, however, remain in existence irrespective of any properties gained or lost; Socrates' ceasing to be a man is not a change in Socrates, but the perishing of Socrates.

The properties that a first substance cannot lose without perishing constitute (approximately) the essence of that first substance (see ESSENTIALISM). These essential properties define a kind to which the first substance belongs. A kind may be a species (*eidos*), for example, man or horse, or a genus (*genos*), for example, animal. In predicating a second substance of a first substance (as in 'Socrates is a man'), we place the first substance in the kind it belongs to. If we predicate one of the contraries that the first substance can lose without perishing, we introduce an item (Socrates' pale colour, his particular height, his ignorance, his being the husband of Xanthippe) in one of the non-substance categories (quality, quantity, relative, and so on). The kinds to which these non-substantial items belong are non-substantial universals.

Aristotle also examines the coming to be and perishing of a first substance. Here again, he distinguishes a persisting subject and two contraries. If we make a statue from bronze, the lump of bronze (the subject) acquires the shape of the statue, and loses the shapelessness it had, and so changes between contraries. But although the lump remains in existence, a new subject, the statue, has come into being. In this case, the subject of the change is the matter (*hylē*), and what it acquires is the form (*eidos*, also rendered 'species').

This analysis of change suggests an argument (*Physics* II 1) to show that the genuine subject, and hence the genuine substance, is the matter, whereas the apparent substance (for example, the statue) is simply matter with a certain shape. Socrates does not become another subject if he changes shape; hence (we may argue) the lump of bronze does not become another subject simply by acquiring the shape of a statue. Similarly, then, a natural organism might be understood as a piece of matter shaped in a certain way so as to embody Socrates. Natural organic 'substances', such as Socrates and this tree, turn out to be not genuine subjects, but mere configurations of the matter that is the real substance.

Aristotle does not endorse this eliminative attitude to natural organic substances. He uses the argument to raise a puzzle about whether matter or form is substance. He discusses this puzzle in *Metaphysics* VII (see §§12–14). This discussion relies on his account of causation and explanation.

9 Causes

When we correctly answer questions such as 'Why does this event happen?' or 'Why is this object as it is?', we state the cause (or explanation; *aition*) of the event or object. Aristotle believes that causes are multivocal (see *Physics* II 3; *Metaphysics* I 3). Different accounts of a cause correspond to different answers to why-questions about (for example) a statue. (1) 'It is made of bronze' states the material cause. (2) 'It is a statue representing Pericles' states the formal cause, by stating the definition that says what the thing is. (3) 'A sculptor made it' states the 'source of change', by mentioning the source of the process that brought the statue into being; later writers call this the 'moving cause' or 'efficient cause'. (4) 'It is made to represent Pericles' states 'that for the sake of which', since it mentions the goal or end for the sake of which the statue was made; this is often called the 'final' (Latin *finis*; 'end') cause.

Each of the four causes answers a why-question. Sometimes (as in our example) a complete answer requires all four causes. Not all four, however, are always appropriate; the (universal) triangle, for example, has a formal cause, stating its definition, but no efficient cause, since it does not come into being, and no final cause, since it is not made to promote any goal or end.

Some have claimed that Aristotle's 'four causes' are not really causes at all, pointing out that he takes an *aition* to be available even in cases where the why-question (for example, 'Why do the interior angles of this figure add up to two right angles?') does not seek what we would call a cause (in Aristotle's division, an efficient cause). When explanations of changes are being sought, however, Aristotle seems to provide recognizably causal explanations. Even the *aitia* (material, formal, final) that do not initially seem to be causes turn

out to play an important role in causal explanation; for this reason, the label 'four causes' gives a reasonably accurate impression of Aristotle's doctrine.

His comparison between artefacts and natural organisms clarifies his claims about formal and final causes. The definition of an artefact requires reference to the goal and the intended function. A hammer's form and essence is a capacity to hammer nails into wood. The hammer was designed to have this capacity for performing this function; and if this had not been its function, it would not have been made in the way it was, to have the properties it has. The form includes the final cause, by specifying the functions that explain why the hammer is made as it is.

Similarly, Aristotle claims, a natural organism has a formal cause specifying the function that is the final cause of the organism. The parts of an organism seem to perform functions that benefit the whole (the heart pumps blood, the senses convey useful information). Aristotle claims that organs have final causes; they exist in order to carry out the beneficial functions they actually carry out. The form of an organism is determined by the pattern of activity that contains the final causes of its different vital processes. Hence Aristotle believes that form as well as matter plays a causal role in natural organisms.

To claim that a heart is for pumping blood to benefit the organism is to claim that there is some causal connection between the benefit to the organism and the processes that constitute the heart's pumping blood. Aristotle makes this causal claim without saying why it is true. He does not say, for instance, either (1) that organisms are the products of intelligent design (as Plato and the Stoics believe), or (2) that they are the outcome of a process of evolution.

Aristotle's account of causation and explanation is expressed in the content and argument of many of his biological works (including those connected with psychology). In the *Parts of Animals* and *Generation of Animals* for instance, he examines the behaviour and structure of organisms and their parts both to find the final causes and to describe the material and efficient basis of the goal-direction that he finds in nature (*Parts of Animals* I 1). He often argues that different physiological processes in different animals have the same final cause.

Some ascribe to Aristotle an 'incompatibilist' view of the relation between final causes and the underlying material and efficient causes. Incompatibilists concede that every goal-directed process (state, event) requires some material process (as nutrition, for example, requires the various processes involved in digesting food), but they argue that the goal-directed process cannot be wholly constituted by any material process or processes; any process wholly constituted by material processes is (according to the incompatibilist) fully explicable in material-efficient terms, and therefore has no final cause.

Probably, however, Aristotle takes a 'compatibilist' view. He seems to believe that even if every goal-directed process were wholly constituted by material processes, each of which can be explained in material-efficient terms, the final-causal explanation would still be the only adequate explanation of the process as a whole. According to this view, final causes are irreducible to material-efficient causes, because the explanations given by final causes cannot be replaced by equally good explanations referring only to these other causes. This irreducibility, however, does not require the denial of material constitution.

10 Change

Aristotle studies nature as an internal principle of change and stability; and so he examines the different types of change (or 'motion'; *kinēsis*) that are found in the natural elements and in the natural organisms composed of them. In *Physics* III 1 he defines change as 'the actuality of the potential *qua* potential'. His definition marks the importance of his views on potentiality (or 'capacity'; *dynamis*) and actuality (or 'realization'; *energeia* or *entelecheia*) (see *Metaphysics* IX 1–9).

The primary type of potentiality is a principle (*archē*) of change and stability. If x has the potentiality F for G, then (1) G is the actuality of F, and (2) x has F because G is the actuality of F. Marathon runners, for instance, have the potentiality to run 26 miles because they have been trained to run this distance; hearts have the capacity to pump blood because this is the function that explains the character of hearts. In these cases, potentialities correspond to final causes.

Potentiality and possibility do not, therefore, imply each other. (1) Not everything that is possible for x realizes a potentiality of x. Perhaps it is possible for us to speak words of Italian (because we recall them from an opera) without having a potentiality to speak Italian (if we have not learnt Italian). (2) Not everything that x is capable of is possible for x; some creatures would still have a potentiality to swim even if their environment lost all its water.

These points about potentiality help to clarify Aristotle's definition of change. The building of a house is a change because it is the actuality of what is potentially built in so far as it is potentially built. 'What is potentially built' refers to the bricks (and so on). The completed house is their complete actuality, and when it is reached, their potentiality to be built is lost. The process of building is their

actuality in so far as they are potentially built. 'In so far . . .' picks out the incomplete actuality that is present only as long as the potentiality to be built (lost in the completed house) is still present. Aristotle's definition picks out the kind of actuality that is to be identified with change, by appealing to some prior understanding of potentiality and actuality, which in turn rests on an understanding of final causation.

In the rest of the *Physics*, Aristotle explores different properties of change in relation to place and time. He discusses infinity and continuity at length, arguing that both change and time are infinitely divisible. He tries to show that the relevant type of infinity can be defined by reference to potentiality, so as to avoid self-contradiction, paradox or metaphysical extravagance. In his view, infinite divisibility requires a series that can always be continued, but does not require the actual existence of an infinitely long series. Once again, the reference to potentiality (in 'can always . . .') has a crucial explanatory role.

11 Metaphysics

Some of the basic concepts of the *Categories* and *Physics* – including substance, particular, universal, form, matter, cause and potentiality – are discussed more fully in the *Metaphysics*. This is a collection of fourteen books, some of them loosely connected. Aristotle probably did not deliver a course of lectures in the order of the present treatise. Parts of book I are almost repeated in book XIII. Book V is a 'philosophical dictionary' that seems to interrupt the argument of books IV and VI. Book XI summarizes parts of book IV. Books II and XI were probably not written entirely by Aristotle.

Still, whatever their literary origins, all these books have a common subject matter, since they all contribute to the universal science that studies the common presuppositions of the other sciences. This universal science has four names. (1) 'First philosophy': it studies the 'first principles' and 'highest causes' (including the four causes of the *Physics*) presupposed by the other sciences. (2) 'The science of being': every science presupposes that it studies some sort of being, and the science of being examines and defends this presupposition. (3) 'Theology': first philosophy is not only first in so far it is most universal, but also in so far as it deals with the primary sort of being, the sort on which all other beings depend. The primary sort of being is substance, and the primary sort of substance is divine substance; hence the science of being must study divine substance. (4) 'Metaphysics' (*ta meta ta physika*; 'the things after the natural things'): it is 'after' or 'beyond' the study of nature because (a) as theology, it studies entities outside the natural order, and (b) as first philosophy, it starts from the study of nature (which is prior and better known 'to us') and goes beyond it to its foundations and presuppositions (which are prior and better known 'by nature'; see §3).

The first three of these names are used by Aristotle himself (*Metaphysics* IV 1–3, VI 1). The fourth was given to the treatise in antiquity (at an uncertain date); its use of 'after' captures Aristotle's different claims about the relation of the universal science to other sciences.

The universal science is the science of being *qua* being – that is, being in so far as it is being – just as mathematics is the science of some beings *qua* mathematical objects (see §16) and physics is the science of some beings *qua* changeable. The science of being studies the beings that are also studied by other sciences, but it isolates the relevant properties of beings by a different level of abstraction; it does not rely on the fact that they have the properties of mathematical or natural objects, but simply on the fact that they are beings studied by a science (*Metaphysics* IV 1–2).

A special science assumes that it begins with a subject that has properties. The universal science is the science of being because it studies the sort of subject that is presupposed by the other sciences; and it is primarily the science of substance because substance is the primary sort of being. Aristotle's analysis of change in *Physics* I introduces substances as subjects; the *Metaphysics* asks what sorts of subjects and substances must be recognized by special sciences.

Aristotle argues that if we are to signify a subject, it is impossible for each of its properties both to belong and not to belong to it. This principle is often called the 'Principle of Non-Contradiction' (*Metaphysics* IV 3–4). To defend the principle, Aristotle considers an opponent who is willing to assert that a single subject, man, is both a bipedal animal and not a biped animal. If the opponent really says this about a single subject, then, when he uses 'man', he must signify one and the same subject, man. If he agrees that in using 'man' he signifies a biped animal, then he cannot also deny that man is a biped animal; for if he denies this, he can no longer say what 'man' signifies, and hence he cannot say what subject it is that he takes to be both a biped animal and not a biped animal. This property (which one cannot also deny of a subject) is an essential property. Hence, the attempt to reject subjects with essential properties is self-undermining.

Subjects of change must also, according to Aristotle, have objective properties (that is, properties that they have whether or not they appear to have them). An argument against Protagoras seeks

to show that any attempt to reject objective properties undermines itself (*Metaphysics* IV 5). Protagoras denies that there are any objective properties, because he claims that how things appear to someone is how they are. If he is to maintain the infallibility of appearances against any possibility of correction, then, Aristotle argues, he must claim that it is possible for the same subject to change in every respect at every time (to match different appearances). This is possible, however, only if the same subject can remain in being, but change in all respects. Aristotle replies that if the same subject persists, it must keep the same essential property (the 'form'); hence it cannot change in every respect (IV 5).

12 From being to substance

In *Metaphysics* IV 2 and VII 1 Aristotle argues that, since substance is the primary type of being and other beings are in some way dependent on substances, the science of being must primarily be concerned with substance. The arguments of IV 4–5 describe some features of substances; they must be subjects with stable, objective, essential properties. Books VII–IX describe these subjects more fully, by re-examining the conception of substance that is presented in the *Categories* and *Physics* (see §§7–8).

Aristotle observes that we regard substance both as 'a this' and as 'essence' (or 'what it is'). We might assume that these two descriptions pick out two sorts of substances – a particular subject ('this') and a universal ('what it is'), corresponding to the first and second substances of the *Categories*. Aristotle, however, insists that his question 'What is substance?' will be satisfactorily answered only when we have found the one thing that best satisfies the conditions for being both a subject (a 'this') and an essence ('what it is'). Whatever best satisfies these conditions is primary substance.

The different candidates that Aristotle considers for this role are matter, form and the compound of the two. He argues against the first and third candidates, and defends the second. He regards matter and compound as types of substance, but argues that they are secondary to form because they do not meet the relevant conditions to the same degree. To show that form is primary substance, he argues that a form is both a subject and an essence of the right sort. In books VIII–IX he clarifies his answer by identifying form with the actuality for which the matter is the potentiality.

13 Why is form substance?

In claiming that form is substance, Aristotle relies on the connections between form, cause, essence and identity. He rejects the eliminative view (§8) that the so-called 'coming-to-be' or 'perishing' of an artefact or organism is simply an alteration of the matter. According to the eliminative view, this alteration does not involve the existence or non-existence of a distinct substance, any more than Socrates' coming to be musical involves the existence of a distinct substance, musical Socrates. Aristotle replies that the production of an artefact and the generation of an organism introduce a new subject, a substance that is neither identical to nor wholly dependent on the matter that constitutes it at a time (see Identity §2). Although this statue of Pericles has come into being from a particular piece of bronze, we may repair the statue by replacing damaged bits; we preserve the same statue but we cause a different bit of bronze to constitute it. Similarly, an organism remains in existence as long as it replaces its matter with new matter: it persists as long as its form persists (*Generation and Corruption* I 5).

When Aristotle speaks of the relation of form to matter, he may refer to either of two kinds of matter: (1) the proximate, organic matter (for example, the organs and limbs making up the organic body); and (2) the remote, non-organic matter (for example, blood, earth, water) of which the organic body is made. Remote matter can exist without the form of the organism, but the organism can persist without any particular piece of remote matter. Proximate matter cannot exist without the form (since it is the function of an arm or heart that makes it the limb or organ it is); the form is the actuality of which the proximate matter is the potentiality (*On the Soul* 412a10; *Metaphysics* 1038b6, 1042b10).

The role of the form in determining the persistence of an organism results from its role as the source of unity. The form, including the organism's vital functions, makes a heap of material constituents into a single organism (*Metaphysics* VII 16). A collection of flesh and bones constitutes a single living organism in so far as it has the form of a man or a horse; the vital functions of the single organism are the final cause of the movements of the different parts. The organism remains in being through changes of matter, as long as it retains its formal, functional properties. Since the structure, behaviour and persistence of the organism must be understood by reference to its form, the form is irreducible to matter (see §9); the organism, defined by its form, must be treated as a subject in its own right, not simply as a heap of matter.

These facts about organisms explain why Aristotle sees a close connection between primary substance and form. Organisms are substances primarily because of their formal properties, not because of their material composition; hence we

cannot identify all the basic subjects there are unless we recognize the reality of formal properties and of subjects that are essentially formal.

14 What are substantial forms?

The conclusion that primary substance and form are closely connected, however, explains only why some substances are essentially formal; it does not explain why form itself is substance. To explain this further claim, we need to decide whether Aristotle regards a substantial form as (1) a species form (shared by all members of a given species, for example, the form of man or horse), normally taken to be a universal, or as (2) a particular form, proprietary to (for example) Socrates. (See *Metaphysics* VII 10–16, XII 5, XIII 10, *Generation of Animals* IV 3, for important evidence.)

Some points favouring the 'universal solution' are the following. (1) Aristotle often contrasts the form with the compound of form and matter, and describes particulars as compounds; hence he apparently does not regard particulars as forms. (2) Similarly, he says that a particular differs from a universal in having both form and matter; hence no particular seems to be simply a form. (3) He says the form is what is specified in a definition, but there is no definition of a particular; hence a particular apparently cannot be a form. (4) He says that substance is prior in knowledge to non-substance, but scientific knowledge of particulars is impossible; hence they apparently cannot be substances, and only a universal can be a substance.

In favour of the 'particular solution' it may be argued: (1) a substance must be a subject, whereas all universals are said of subjects; (2) a substance must be a 'this', as opposed to a 'such', and hence, apparently, some sort of particular; (3) Aristotle argues at length that no universal can be a substance.

We might be tempted to conclude that Aristotle's position is inconsistent. His conviction that substance as 'this' and substance as 'what is it' must be the same thing leads him to insist that the successful candidate for substance must satisfy the criteria for being both a this (a subject, and hence a particular) and an essence (a property, and hence a universal). If one and the same thing cannot satisfy both criteria, then no one thing can satisfy all Aristotle's conditions for being a substance.

We need not draw this conclusion, however. We can maintain that Aristotle consistently favours the universal solution, if we can show: (1) a 'this' need not be a particular; (2) some universals are subjects; (3) a species form is not the sort of universal that cannot be a substance.

We can maintain that he consistently favours the particular solution, if we can show the following. (1) The contrast between form and matter does not imply that they are always mutually exclusive; some forms may be constituted by, or embodied in, particular bits of matter. Sometimes, indeed, Aristotle speaks as though a form is a subject that can persist and perish and can exchange its matter. (2) The sense in which particulars do not allow definition and scientific knowledge does not prevent them from also being, in an appropriate sense, prior in definition and knowledge to universals (*Metaphysics* XIII 10 may attribute the relevant priority to particular substances).

These two solutions are different ways of expressing Aristotle's belief that substances are basic. Both his metaphysics and his natural philosophy express and defend the conviction that natural organisms and their kinds are substances because they are fundamental; they are fundamental because they are irreducible to their constituent matter. It is more difficult to decide whether the individuals or their kinds are more fundamental. Perhaps, indeed, we ought not to decide; different things may be fundamental or irreducible in different ways.

15 Universals, Platonic Forms, mathematics

These disputes partly concern Aristotle's attitude to the reality of universals. One-sided concentration on some of his remarks may encourage a nominalist or conceptualist interpretation (see NOMINALISM). (1) He rejects Plato's belief (as he understands it) in separated universal Forms (see PLATO §§10, 12–16; FORMS, PLATONIC), claiming that only particulars are separable. (2) In *Metaphysics* VII 13–16 he appears to argue that no universal can be a substance. (3) He claims that the universal as object of knowledge is – in a way – identical to the knowledge of it (*On the Soul* 417b23).

Other remarks, however, suggest realism about universals. (4) He claims they are better known by nature; this status seems to belong only to things that really exist. (5) He believes that if there is knowledge, then there must be universals to be objects of it; for our knowledge is about external nature, not about the contents of our own minds.

Aristotle's position is consistent if (1)–(3) are consistent with the realist tendency of (4)–(5). The denial of separation in (1) allows the reality of universals. Similarly, (2) may simply say that no universals are primary substances (which are his main concern in *Metaphysics* VII). And (3) may simply mean (depending on how we take 'in a way') that the mind's conception of the extra-mental universal has some of the features of the universal (as a map has some of the features of the area that it maps). While Aristotle denies that universals can exist without sensible particulars to embody them,

he believes they are real properties of these sensible particulars.

He offers a rather similar defence of the reality, without separability, of mathematical objects (*Physics* II 2; *Metaphysics* XIII 3). While agreeing with the Platonist view that there are truths about, for example, numbers or triangles that do not describe the sensible properties of sensible objects, he denies that these truths have to be about independently-existing mathematical objects. He claims that they are truths about certain properties of sensible objects, which we can grasp when we 'take away' (or 'abstract') the irrelevant properties (for example, the fact that this triangular object is made of bronze). Even though there are no separate objects that have simply mathematical properties, there are real mathematical properties of sensible objects.

16 Metaphysics: God

When Aristotle claims that first philosophy is also theology (see §11), he implies that the general discussion of being and substance is the basis for the special discussion of divine substance. (Hence later writers distinguish 'special metaphysics', dealing with God, from 'general metaphysics', dealing with being in general.) The different features of substance explained in *Metaphysics* VII–IX are included in the divine substance of XII. (1) Primary substance is to be identified in some way with form rather than with matter or with the compound of form and matter; divine substance is pure form without matter. (2) Primary substance is in some way numerically one, a 'this' rather than a 'such'; divine substance is completely one and indivisible. (3) Primary substance is in some way actuality rather than potentiality; divine substance is pure actuality with no potentiality. (4) Primary substance is soul rather than body (see §17); divine substance is pure intellect without sense or body.

In each case the properties of primary substance are found in a sensible substance (an animal or a plant) only in so far as they belong to an object that also has other properties; hence primary substance in sensible reality is the form and actuality of an object (a horse, for example) that also has matter and potentiality. In divine substance, however, each feature is found in separation from these other properties; that is why a divine substance lacks matter, multiplicity, parts or potentiality. Aristotle argues that a substance with these pure substantial properties must exist if any sensible substances are to exist; for the existence of potentialities that can be actualized presupposes the existence of an actuality that does not itself include any potentiality (to avoid an infinite regress).

Since this primary type of substance is divine, it is what traditional belief in the Olympian gods was about, what the Presocratics were talking about when they spoke of 'the divine', and what Plato was talking about in speaking of a supreme god. Aristotle mentions the traditional Olympian gods without committing himself to acceptance of the traditional conception of them. He rejects anthropomorphic views of the gods, but he speaks of the divine nature as a kind of mind. He believes that there is something divine about the order and workings of nature, and still more divine in the heavenly substances (*Parts of Animals* I 5). Although he continues to speak of gods in the plural, he also speaks of one divine mind as the ultimate cause of the whole universe; these remarks help to justify the later interpreters who take him to speak of the one God who is the subject of (for example) Aquinas' 'Five Ways' (*Summa theologiae* 1a q.2 a.3) (see AQUINAS, T. §11).

Aristotle's God is the ultimate cause of the physical universe, but not its creator (as Plato's demiurge is), since Aristotle believes the universe is eternal. Nor does Aristotle suggest that God has providence or foreknowledge concerned with future contingent events. But he believes that the physical universe is dependent on God. In *Physics* VIII he argues that the explanation of motion requires recognition of a first cause of motion, and in *Metaphysics* XII this first cause is identified with divine, immaterial, substance. This first mover is itself unmoved; it initiates motion only as an object of love initiates motion by attraction. It is the ultimate final cause of the various movements in the universe.

In treating the divine substance as a god, and hence as a being with a soul and an intellect, Aristotle attributes some mental life to it. But since it would be imperfect if it thought of objects outside itself (because it would not be self-sufficient), it thinks only of its own thinking. This restriction, however, is not as severe as it may seem, since Aristotle believes that the various objects of thought are in some way identical to the mind that thinks them (see §15). In so far as God thinks of his own mind, he thereby also contemplates the order of the universe as a whole; this is the order that the different movements in the universe seek to embody.

Sometimes (as in *Physics* VIII) Aristotle argues for a single first mover. In *Metaphysics* XII, however, he argues that an unmoved mover must be postulated for each of the distinct movements of the heavenly bodies. This astronomical interpretation of his theological doctrine is difficult to reconcile with his belief, reaffirmed in *Metaphysics* XII 10, that in some way the universe is unified by a single first unmoved mover.

17 Soul and body

Aristotle's treatise *On the Soul* is placed among the works on natural philosophy, but should be read with *Metaphysics* VII–IX. In Aristotle's view, disputes about soul and body are simply a special case of the more general disputes about form and matter. He rejects both the Presocratic materialist assumption that the soul is simply non-organic matter, and the Platonic dualist claim that it must be something entirely non-bodily. He argues that soul is substance because it is the form of a natural body, and that the body is the matter informed by the soul. Although the soul is a substance distinct from the non-organic body (the collection of non-organic matter belonging to a living organism; see §13), it is not immaterial (if being immaterial excludes being composed of matter), nor is it independent of some non-organic body or other.

Aristotle assumes that the soul is the primary principle of life, and hence that it distinguishes the living from the non-living. A living organism is nourished, grows and diminishes, through itself – from a causal origin within itself rather than from the action of external agents. A living organism must, therefore, be teleologically ordered, since (for Aristotle) nutrition and growth cannot be understood without appeal to final causation (see TELEOLOGY).

If life must be conceived teleologically, and the soul is the *primary* principle of life, then the soul is form rather than matter. For the primary principle is whatever explains our vital activities; since these are goal-directed activities, their explanation must refer to the goal-directed features of the subject, and so to the form rather than the matter. If the soul is what we live by primarily, it must be the final cause of the body, and so a formal, not a material, aspect of the subject. Soul must, therefore, be substance as form.

Aristotle attributes to the soul the features of substantial form (see §13). (1) It is a substance that is irreducible to a material non-organic body (remote matter); to that extent the soul is incorporeal, and not just some ordinary material stuff. (2) It is the source of unity that makes a heap of material constituents into a single organism. For a collection of flesh and bones constitutes a single living organism in so far as it is teleologically organized; the activities of the single organism are the final cause of the movements of the different parts. Since a single organism has a single final cause, it has a single soul and a single body. (3) The identity and persistence of the soul determine the identity and persistence of the creature that has it. If something has a soul in so far as it has life, then Socrates perishes if and only if his soul does. The truth of this Platonic claim (*Phaedo* 115c–e) does not imply Platonic dualism. (4) The definition of a soul must mention the proximate material subject (the organic body and its parts) whose capacities are actualized in the functions of the organism (*Metaphysics* 1036b28–30). A soul must be non-coincidentally connected to a specific sort of organic body (*On the Soul* 407b20–4).

Some of the puzzles in Aristotle's doctrine of substantial form arise in his doctrine of soul and body. If, for instance, he recognizes particular substantial forms, then he also recognizes (as the previous paragraph assumes) the individual souls of Socrates and Callias; if, however, he recognizes only one substantial form for each species, then he recognizes only one soul for human beings, another for horses, and so on.

Since the soul is the form of the living body, an account of the different 'parts' or 'capacities' (or 'faculties'; *dynameis*) of the soul does not describe the different physiological processes underlying the different activities of a living organism, but describes their formal and goal-directed aspects. Aristotle describes the capacities that distinguish the different types of souls: nutrition (characteristic of plants), perception and appearance (characteristic of animals) and rational thought (characteristic of rational animals) (see PSYCHĒ). He describes some of the physiological bases of these psychic capacities in the shorter treatises on natural philosophy, including the *Parva Naturalia*, the *Movement of Animals* and the *Progression of Animals*.

18 Perception

To define perception, Aristotle returns to his contrast between form and matter. Perception happens in so far as (1) the perceiver becomes like the object (*On the Soul* 417a18); (2) the perceiver that was potentially *F* (for example, white) becomes actually *F* when it perceives the actually *F* object (418a3); (3) the perceiver acquires the form, but not the matter, of the object (424a18–24). These descriptions express a realist view of perception and its objects; Aristotle assumes in (2) that an object is actually white, square, and so on in its own right, before we perceive it.

He is sometimes taken to imply in (1) that perception requires physical similarity; but (3) counts against this interpretation. A sense receives the form without the matter in the way in which a house without matter is in the soul of the architect before the house is built. In the latter case, nothing that looks like a house is in the builder, but features of the house correspond to features of the builder's design. Similarly, when we hear a tune, our ears do not necessarily sound like the tune, but a state of us

systematically corresponds to the tune (as features of a map correspond to features of the area it maps).

A 'common sense' perceives common properties of sensible objects, such as size, shape and number, which are all perceived through the perception of motion (*On the Soul* 425a14–20). This is not a sixth sense independent of the other five, but the result of the cooperation of the five senses. Aristotle argues that we can explain our grasp of these common properties without supposing that they are objects of intellect rather than sense (contrast Plato, *Theaetetus* 184–6).

19 Appearance and thought

Appearance (or 'imagination'; *phantasia*) links perception to goal-directed movement. A lion sees or smells a deer; it takes pleasure in the prospect of eating the deer, and so wants to catch the deer. To connect perception with pleasure and desire, we need to say how the deer appears to the lion (as prey); this is what Aristotle calls the lion's appearance of the deer (*On the Soul* III 3, 7).

Aristotle denies that this appearance constitutes a belief (*doxa*). He argues that belief requires reason and inference, which non-human animals lack; in his view, they lack any grasp of a universal, and have only appearances and memory of particulars (*Nicomachean Ethics* 1147b4–5). The operations of sense, memory and experience are necessary, but not sufficient, for the grasp of a universal that is expressed in concepts and beliefs (*Posterior Analytics* II 19; *Metaphysics* I 1).

Concepts and beliefs require intellect (*nous*) actualized in 'understanding' or 'thinking' (*noein*; *On the Soul* III 4) (see NOUS). Thought differs from perception in so far as it grasps universal essences – for example, what flesh is, as opposed to flesh itself. Perception does not include grasp of the universal as such; in grasping the universal, we recognize some feature of our experience as a ground for attributing the universal to a particular that we experience.

To explain how the mind is capable of grasping universals when we interact causally with particular perceptible objects, Aristotle distinguishes two aspects of intellect – passive and 'productive' (or 'active' or 'agent') – claiming that these two aspects must combine to produce thought of universals (*On the Soul* III 5). He does not say how productive intellect contributes to our grasp of universals. Later interpreters suggest that productive intellect abstracts the aspects relevant to the universal from the other features of particulars that are combined with them in perception (Aquinas, *Summa theologiae* 1a q.79 a.3).

Aristotle takes the presence of this productive intellect to be necessary for any thinking at all. Moreover, he believes that productive intellect is capable of existing without a body. He still maintains his belief in the inseparability of soul from body; for since productive intellect is not a type of soul, its separate existence is not the separate existence of a soul.

20 Desire and voluntary action

Perception, appearance and thought are connected to goal-directed movement by means of desire. The appearance of something as desirable is the source of an animal's tendency to pursue one sort of thing rather than another. External objects, however, appear desirable to different agents in different ways. Aristotle distinguishes the appetite (*epithymia*) that animals have from the wish (rational desire; *boulēsis*) that only rational agents have; appetite is for the pleasant and wish is for the good (*On the Soul* 414b2–6, 432b5–7, *Politics* 1253a15–18).

A rational agent's wish differs from appetite in so far as it is guided by deliberation resting on one's conception of one's good. Such a conception extends beyond one's present inclinations both at a particular time and over time. Rational agents are aware of themselves as extending into past and future. Deliberation that is guided by reference to these broader aspects of one's aims and nature results in the rational choice that Aristotle calls 'decision' (*prohairesis*; *Nicomachean Ethics* III 3).

Agents who act on desire and appearance also act voluntarily (*hekousiōs*), in so far as they act on some internal principle (*archē*). While voluntary action is not confined to rational agents, their voluntary action has special significance, because it is an appropriate basis for praise and blame. Since it has an internal principle, it is in our control as rational agents, and therefore we are justly praised and blamed for it. We are held responsible for our actions in so far as they reflect our character and decisions (*Nicomachean Ethics* III 1–5).

Aristotle's defence of his belief that we are appropriately responsible agents does not confront the questions later raised by Epicurus' claim that responsibility is incompatible with the complete causal determination of our actions (see EPICUREANISM). An incompatibilist position is ascribed to Aristotle by Alexander in *On Fate*. Aristotle neither explicitly presents an incompatibilist position nor explicitly endorses a compatibilist position of the sort later defended by the Stoics.

A discussion of time, truth and necessity (the 'Sea Battle'; *De Interpretatione* 9) has suggested to some interpreters that Aristotle is an indeterminist. His opponent is a fatalist, who assumes that (1) future-tensed statements about human actions (for example, 'There will be a sea battle tomorrow') were true in the past, and infers that (2) the future is necessarily

determined, independently of what we choose. Aristotle certainly rejects (2). If he accepts the validity of the fatalist's argument, and rejects (1), then he accepts indeterminism.

An alternative reply to the fatalist would be to accept (1) and to deny the validity of the argument. We might argue that the past truth of statements about my actions does not imply that my actions are determined independently of my choices. If on Friday Socrates decides to walk, and he acts on his decision on Friday, then it was true on Thursday that Socrates would walk on Friday, and also true that on Friday he would act on his decision to walk, but it was not true on Thursday that he would walk whether or not he decided to (see STOICISM). Probably Aristotle accepts this alternative reply to the fatalist, and hence does not endorse indeterminism.

21 The human good

Aristotle's account of rational agents, choice, deliberation and action is an appropriate starting point for his ethical theory. Ethics is concerned with the praiseworthy and blameworthy actions and states of character of rational agents; that is why it concerns virtues (praiseworthy states) and vices (blameworthy states) (see ARETĒ).

Aristotle's ethical theory is mostly contained in three treatises: the *Magna Moralia*, the *Eudemian Ethics* and the *Nicomachean Ethics*. The titles of the last two works may reflect a tradition that Eudemus (a member of the Lyceum) and Nicomachus (the son of Aristotle and Herpyllis) edited Aristotle's lectures. The *Magna Moralia* is widely agreed not to have been written by Aristotle; some believe, with good reason, that it contains a student's notes on an early course of lectures by Aristotle. The *Eudemian Ethics* is now widely agreed to be authentic, and generally (not universally) and reasonably taken to be earlier than the *Nicomachean Ethics*. Three books (*Nicomachean Ethics* V–VII = *Eudemian Ethics* IV–VI) are assigned by the manuscripts to both the *Eudemian Ethics* and the *Nicomachean Ethics*.

Aristotle conceives 'ethics' (*Magna Moralia* 1181a24) as a part of political science; he treats the *Nicomachean Ethics* and the *Politics* as parts of a single inquiry (*Nicomachean Ethics* X 9). Ethics seeks to discover the good for an individual and a community (*Nicomachean Ethics* I 2), and so it begins with an examination of happiness (*eudaimonia*). ('Wellbeing' and 'welfare' are alternative renderings of *eudaimonia* that may avoid some of the misleading associations carried by 'happiness'; see EUDAIMONIA.) Happiness is the right starting point for an ethical theory because, in Aristotle's view, rational agents necessarily choose and deliberate with a view to their ultimate good, which is happiness; it is the end that we want for its own sake, and for the sake of which we want other things (so that it is the ultimate non-instrumental good). If it is to be an ultimate end, happiness must be complete (or 'final'; *teleion*) and self-sufficient (*Nicomachean Ethics* I 1–5, 7).

To find a more definite account of the nature of this ultimate and complete end, Aristotle argues from the human function (*ergon*), the characteristic activity that is essential to a human being in the same way that a purely nutritive life is essential to a plant and a life guided by sense perception and desire is essential to an animal (*Nicomachean Ethics* I 7). Since a human being is essentially a rational agent, the essential activity of a human being is a life guided by practical reason. The good life for a human being must be good for a being with the essential activity of a human being; hence it must be a good life guided by practical reason, and hence it must be a life in accordance with the virtue (*aretē*) that is needed for achieving one's good. The human good, therefore, is an actualization of the soul in accordance with complete virtue in a complete life. This 'complete virtue' appears to include the various virtues described in the following books of the *Nicomachean Ethics*; this appearance, however, may be challenged by *Nicomachean Ethics* X (see §26).

22 Virtue of character

From the general conception of happiness Aristotle infers the general features of a virtue of character (*ēthikēaretē*; *Nicomachean Ethics* I 13). He agrees with Plato in recognizing both rational and non-rational desires (see PLATO §14). One's soul is in a virtuous condition in so far as the non-rational elements cooperate with reason; in this condition human beings fulfil their function well. The argument from the human function does not make it clear what states of a rational agent count as fulfilling the human function. Aristotle seeks to make this clearer, first through his general account of virtue of character, and then through his sketches of the individual virtues.

A virtue of character must be a 'mean' or 'intermediate' state, since it must achieve the appropriate cooperation between rational and non-rational desires; such a state is intermediate between complete indulgence of non-rational desires and complete suppression of them. (Aristotle is not recommending 'moderation' – for example, a moderate degree of anger or pleasure – in all circumstances.) The demand for cooperation between desires implies that virtue is more than simply control over desires; mere control is 'continence' (*enkrateia*) rather than genuine virtue.

The task of moral education, therefore, is to harmonize non-rational desires with practical reason. Virtuous people allow reasonable satisfaction to their appetites; they do not suppress all their fears; they do not disregard all their feelings of pride or shame or resentment (*Nicomachean Ethics* 1126a3–8), or their desire for other people's good opinion. Aristotle's sketches of the different virtues show how different non-rational desires can cooperate with practical reason.

23 Virtue, practical reason and incontinence

A virtuous person makes a decision (*prohairesis*) to do the virtuous action for its own sake. The correct decision requires deliberation; the virtue of intellect that ensures good deliberation is prudence (or 'wisdom', *phronēsis*; *Nicomachean Ethics* VI 4–5); hence the mean in which a virtue lies must be determined by the sort of reason by which the prudent person would determine it (1107a1–2). Virtue of character is, therefore, inseparable from prudence. Each virtue is subject to the direction of prudence because each virtue aims at what is best, as identified by prudence.

In claiming that prudence involves deliberation, Aristotle also emphasizes the importance of its grasping the relevant features of a particular situation; we need to grasp the right particulars if deliberation is to result in a correct decision about what to do here and now. The right moral choice requires experience of particular situations, since general rules cannot be applied mechanically. Aristotle describes the relevant aspect of prudence as a sort of perception or intuitive understanding of the right aspects of particular situations (*Nicomachean Ethics* VI 8, 11).

These aspects of prudence distinguish the virtuous person from 'continent' and 'incontinent' people (*Nicomachean Ethics* VII 1–10). Aristotle accepts the reality of incontinent action (*akrasia*), rejecting Socrates' view that only ignorance of what is better and worse underlies apparent incontinence (see Socrates §6; Akrasia). He argues that incontinents make the right decision, but act contrary to it. Their failure to stick to their decision is the result of strong non-rational desires, not simply of cognitive error. Still, Aristotle agrees with Socrates in believing that ignorance is an important component of a correct explanation of incontinence, because no one can act contrary to a correct decision fully accepted at the very moment of incontinent action.

The error of incontinents lies in their failure to harmonize the demands of their appetites with the requirements of virtue; their strong appetites cause them to lose part of the reasoning that formed their decision. When they act, they fail to see clearly how their general principles apply to their present situation. If their failure results from an error in deliberation, it is clear why Aristotle insists that incontinent people lack prudence.

24 Choice, virtue, and pleasure

It is initially puzzling that virtuous people decide to act virtuously for its own sake as a result of deliberation. If they decide on virtuous action for its own sake, then their deliberation causes them to choose it as an end in itself, not simply as a means. Decision and deliberation, however, are not about ends but about 'the things promoting ends' (*ta pros ta telē*, often rendered 'means to ends'). Aristotle's description of the virtuous person, then, seems to attribute to decision a role that is excluded by his explicit account of decision.

This puzzle is less severe once we recognize that Aristotle regards different sorts of things as 'promoting' an end. Sometimes he means (1) that the action is external and purely instrumental to the end; in this way buying food 'promotes' eating dinner. Sometimes, however, he means (2) that the action is a part or component of the end, or that performing the action partly constitutes the achieving of the end; in this way eating the main course 'promotes' eating dinner. Deliberation about this second sort of 'promotion' shows that an action is worth choosing for its own sake, in so far as it partly constitutes our end.

This role for deliberation explains how virtuous people can decide, as a result of deliberation, on virtuous action for its own sake; they choose it as a part of happiness, not as a merely instrumental means. Prudence finds the actions that promote happiness in so far as they are parts of the happy life. Such actions are to be chosen for their own sake, as being their own end; they are not simply instrumental means to some further end. The virtuous person's decision results from deliberation about the composition of happiness; virtuous people decide on the actions that, by being non-instrumentally good, are components of happiness in their own right.

Aristotle's demand for the virtuous person to decide on the virtuous action for its own sake is connected with two further claims: (1) the virtuous person must take pleasure in virtuous action as such; (2) in doing so, the virtuous person has the pleasantest life. In these claims Aristotle relies on his views about the nature of pleasure and its role in happiness (*Nicomachean Ethics* VII 11–14, X 1–5).

He denies that pleasure is some uniform sensation to which different kinds of pleasant action are connected only causally (in the way that the reading of many boring books on different subjects

might induce the same feeling of boredom). Instead he argues that the specific pleasure taken in *x* rather than *y* is internally related to doing *x* rather than *y*, and essentially depends on pursuing *x* for *x*'s own sake. Pleasure is a 'supervenient end' (1174b31–3) resulting from an activity that one pursues as an activity (*praxis* or *energeia*) rather than a mere process or production (*kinēsis* or *poiēsis*).

Aristotle insists, following Plato's *Philebus*, that the value of the pleasure depends on the value of the activity on which the pleasure supervenes (1176a3–29). The virtuous person has the pleasantest life, but the pleasantest life cannot aim exclusively at pleasure.

25 Virtue, friendship and the good of others

The virtuous person's deliberation, identifying the mean in relation to different desires and different situations, is articulated in the different virtues of character (described in *Nicomachean Ethics* III–V). The different virtues are concerned with the regulation of non-rational desires (for example, bravery, temperance, good temper), external goods (for example, magnificence, magnanimity) and social situations (for example, truthfulness, wit). Some concern the good of others to some degree (bravery, good temper, generosity).

Aristotle's Greek for virtue of character, *ēthikēaretē*, is rendered into Latin as 'virtus moralis'. The English rendering 'moral virtue' is defensible, since the virtues of character as a whole display the impartial concern for others that is often ascribed to morality. They are unified by the aim of the virtuous person, who decides on the virtuous action because it is 'fine' (*kalon*). Fine action systematically promotes the good of others; we must aim at it if we are to find the mean that is characteristic of a virtue (1122b6–7).

A second unifying element in the virtues, inseparable from concern for the fine, is their connection to justice (V 1–2). Aristotle takes justice to be multivocal (see §4), and distinguishes general justice from the specific virtue concerned with the prevention and rectification of certain specific types of injustices. General justice is the virtue of character that aims specifically at the common good of a community. Since it is not a different state of character from the other virtues, they must incorporate concern for the common good.

To explain why concern for the good of others, and for a common good, is part of the life that aims at one's own happiness, Aristotle examines friendship (*philia*; *Nicomachean Ethics* VIII–IX). All three of the main types of friendship (for pleasure, for advantage and for the good) seek the good of the other person. Only the best type – friendship for the good between virtuous people – includes *A*'s concern for *B*'s good for *B*'s own sake and because of *B*'s essential character (*Nicomachean Ethics* VIII 1–4).

In the best sort of friendship, the friend is 'another self'; *A* takes the sorts of attitudes to *B* that *A* also takes to *A*. Aristotle infers that friendship is part of a complete and self-sufficient life (IX 9–11). Friendship involves sharing the activities one counts as especially important in one's life, and especially the sharing of reasoning and thinking. Friends cooperate in deliberation, decision and action; and the thoughts and actions of each provide reasons for the future thoughts and actions of the other. The cooperative aspects of friendship more fully realize each person's own capacities as a rational agent, and so promote each person's happiness. Hence the full development of a human being requires concern for the good of others.

26 Two conceptions of happiness?

Although Aristotle emphasizes the other-regarding, social aspects of happiness, he also advocates pure intellectual activity (or 'study', *theōria*) – the contemplation of scientific and philosophical truths, apart from any attempt to apply them to practice (*Nicomachean Ethics* X 6–8). The connection between the human function and human happiness (see §21) implies that contemplation is a supremely important element in happiness. For contemplation is the highest fulfilment of our nature as rational beings; it is the sort of rational activity that we share with the gods, who are rational beings with no need to apply reason to practice. Aristotle infers that contemplation is the happiest life available to us, in so far as we have the rational intellects we share with gods (see §16).

According to one interpretation, Aristotle actually identifies contemplation with happiness: contemplation is the only non-instrumental good that is part of happiness, and the moral virtues are to be valued – from the point of view of happiness – simply as means to contemplation. If this is Aristotle's view, it is difficult to see how the virtues of character are even the best instrumental means to happiness. Even if some virtuous actions are instrumental means to contemplation, it is difficult to see how the motives demanded of the virtuous person (see §§24–5) are always useful, rather than distracting, for those who aim at contemplation.

Probably, however, Aristotle means that contemplation is the best component of happiness. If we were pure intellects with no other desires and no bodies, contemplation would be the whole of our good. Since, however, we are not in fact merely intellects (*Nicomachean Ethics* 1178b3–7), Aristotle recognizes that the good must be the good of the

whole human being. Contemplation is not the complete good for a human being.

If this is Aristotle's view, then contemplation fits the conception of happiness that is upheld in the rest of the *Nicomachean Ethics* and in the other ethical works. The virtues of character, and the actions expressing them, deserve to be chosen for their own sakes as components of happiness. In the virtuous person, they regulate one's choice of other goods, and so they also regulate one's choices about contemplation. The *Politics* may be taken to develop this conception of happiness, since (in book VII) it sets contemplation in the context of a social order regulated by the moral virtues.

27 Politics: ideal states

The *Politics* pursues three connected aims: (1) it completes the discussion of happiness, by showing what kind of political community achieves the human good (mainly books I, II and VII); (2) it sets out moral and political principles that allow us to understand and to criticize the different sorts of actual states and their constitutions (mainly books III and IV); (3) it offers some proposals for improving actual states (mainly books V and VI). The order of the books probably reflects Aristotle's aim of describing an ideal state after examining the strengths and weaknesses of actual states.

An individual's desire for happiness leads eventually to the city. A human being is a 'political animal', because essential human capacities and aims are completely fulfilled only in a political community; hence (given the connection between the human function and the human good) the individual's happiness must involve the good of fellow members of a community. The relevant sort of community is a *polis* ('city' or 'state') – a self-governing community whose proper function (not completely fulfilled by every actual political community) is to aim at the common good of its citizens, who (normally) share in ruling and in being ruled. The city is the all-inclusive community, of which the other communities are parts, since it aims at advantage not merely for some present concern but for the whole of life (*Nicomachean Ethics* 1160a9–30). Since happiness is complete and self-sufficient, the city is a complete and self-sufficient community (*Politics* 1252b28), aiming at a complete and self-sufficient life that includes all the goods needed for a happy life.

The connection between human nature, human good and the political community is most easily understood from Aristotle's account of friendship. Complete friendship, which requires living together and sharing rational discourse and thought, is restricted to individuals with virtuous characters, but this is not the only type of friendship that achieves self-realization in cooperation; a similar defence can be given for the friendship of citizens. Collective deliberation about questions of justice and benefit contributes to the virtuous person's self-realization because it extends the scope of one's practical reason and deliberation beyond one's own life and activities. Since the city is comprehensive, seeking to plan for everything that is needed for the complete good, a rational agent has good reason to want to share in its deliberations.

Since, then, Aristotle believes that political activity contributes in its own right to the human good, he argues against a 'social contract' theory that assigns a restricted instrumental function to the state (safety, or mutual protection, or the safeguarding of what justly belongs to each person; *Politics* III 9). Political life is to be valued for itself, apart from any instrumental benefit; the best city aims at the development of the moral virtues and at the political participation of all who are capable of them.

In the light of these aims, Aristotle describes the best city. It has to assume favourable external conditions (geographical and economic) to allow the development of political life. Its criteria for citizenship are restricted, since they exclude everyone (including women and manual labourers) whom Aristotle regards as incapable of developing the virtues of character. Within the class of citizens, however, Aristotle is concerned to avoid gross inequality of wealth and to ensure that everyone shares both in ruling and in being ruled. The institutions of the best state provide the political, social, economic and educational basis for the practice of the moral virtues and for contemplation.

28 Politics: imperfect states

Just as a correct conception of happiness is the basis of the ideal city, various incorrect conceptions of happiness define mistaken aims for different cities. These mistaken aims underlie the different conceptions of justice that are embodied in the constitutions of different cities. Partisans of oligarchy, for instance, take happiness to consist in wealth; they treat the city as a business partnership (*Politics* 1280a25–31). Partisans of democracy take happiness to consist simply in the satisfaction of desire; they assume that if people are equal in the one respect of being free rather than slaves, they are equal altogether, and should have an equal share in ruling (1280a24–5). Neither view is completely mistaken, since neither wealth nor freedom is irrelevant to questions of justice, but each is one-sided.

These one-sided views cause errors about the just distribution of political power or other goods. The

proper basis for assigning worth in distribution will be whatever is relevant for the common good, since that is the aim of general justice. Since a correct conception of the common good requires a correct conception of happiness, a correct answer to the question about distribution must appeal to a true conception of happiness.

The criticism of existing constitutions seeks to show both how they fall short of the norms that are met by the ideal state, and how they can be improved. Aristotle wants to describe not only the ideal state, but also the best organization of each political system. In some circumstances, he believes, economic, social and demographic facts may make (for example) democracy or oligarchy difficult to avoid. Still, an imperfect constitution can be improved, by attention to the aspects of justice, and hence the aspects of happiness, that this constitution tends to ignore. Even when Aristotle may appear to be engaged in empirical political sociology, or to be offering hints for the survival of a particular regime, he is guided by the moral and political principles that he defends in the more theoretical parts of the *Politics*.

29 Rhetoric and poetics

In Aristotle's classification, rhetoric and poetics (*poiētikē*; literally 'productive') count as 'productive' rather than 'practical' disciplines; they are concerned with 'production' (*poiēsis*) – purely instrumental action aiming at some external end – rather than with 'action' (*praxis*) – action that is also an end in itself. Rhetoric is a productive discipline in so far as it aims at persuasion in public speaking, and seeks the arguments, diction, language, metaphor, appeals to emotion and so on, that are most likely to persuade different types of audiences. Hence Aristotle's treatise on rhetoric contains sections on these different topics. Dialectic and logic are useful to a student of rhetoric, even though rhetoric does not aim at the truth; for true or plausible claims tend to be persuasive. *Rhetoric* II deals with another aspect of rhetorical persuasion, by describing the different emotions; the student of rhetoric must know how to arouse emotions in an audience.

Aristotle also takes his moral and political theory to be relevant to rhetoric, for two main reasons. (1) Rhetoric is concerned with the moral and political issues discussed in public assemblies or in courts, and the orator needs to be familiar with the convictions of a given audience. (2) Even more important, the orator should be guided by correct moral and political convictions (without necessarily grasping their philosophical basis). Aristotle does not endorse the conception of oratory as a technique of persuasion that is indifferent to the moral and political aims that it serves. This conception of oratory arouses Plato's criticism in the *Gorgias* (see PLATO §7) Aristotle replies to such criticism by arguing that the orator should learn, and should be guided by, correct principles. He sets out some of these in the *Rhetoric*.

Moral and political principles are also relevant to Aristotle's treatment of literary criticism in the *Poetics*. The surviving part of this treatise deals mainly with tragedy. Some of it is similar to the *Rhetoric*, in so far as it discusses matters of technique and psychology; Aristotle describes the various sorts of plots, characters and dramatic devices that affect the audience in different ways. He is also concerned, however, about the moral aspects of tragedy; in this he may be responding to the criticisms of tragedy in book X of Plato's *Republic*. He argues that tragedy achieves its appropriate effect when it directs pity, fear, sympathy and revulsion at the appropriate sorts of people and situations; and he examines the plots and characters of various tragedies from this point of view (see KATHARSIS; MIMĒSIS).

30 Influence

Some aspects of Aristotle's philosophy have become so familiar that we do not even attribute them to him. When we say that an event was a mere 'coincidence', or that an ignorant person is 'ill-informed', or that someone's behaviour is forming good or bad 'habits', our vocabulary expresses Aristotelian assumptions, transmitted through Latin translations and interpretations.

The explicit influence of Aristotle's philosophical works and theories has been variable. In Hellenistic philosophy, he is not prominently cited or discussed; some have even doubted whether the major Stoics knew his works. From the first century BC, however, the study of Aristotle revived. This revival produced philosophers defending an Aristotelian position, often incorporating Stoic or Platonist elements, but sometimes sharpening contrasts between Aristotle and the Hellenistic schools. These Aristotelians began a long series of Greek commentaries (lasting until the sixth century AD). Many of the later commentators were Neoplatonists; some of whom tried to reconcile Aristotelian with Platonic doctrines (see NEOPLATONISM; PORPHYRY).

Between the sixth and the thirteenth centuries, most of Aristotle's works were unavailable in western Europe, although he was still studied in the Byzantine empire and the Islamic world. Two leading figures in the revival of Aristotelian studies and of Aristotelian philosophy in medieval Europe were the translator William of Moerbeke and Thomas

Aquinas. Aquinas' attempt to combine Aristotelian philosophy with orthodox Christian theology was at first rejected by ecclesiastical authority, but then came to be accepted (see AQUINAS, T.).

The 'scholastic' philosophy of Aquinas and his successors is often opposed, but often presupposed, by Descartes, Locke, Hobbes and many of their successors, who often do not distinguish it from Aristotle's own philosophy. The reader who compares their representation of the scholastic position with Aristotle's own works (or with Aquinas) will often be surprised by the sharp differences between Aristotle's (and Aquinas') own positions and the positions that are attributed to him by the seventeenth-century philosophers who reject his authority.

Modern historical study of Aristotle begins in the early nineteenth century. It has led to philosophical reassessment, and his works have once again become a source of philosophical insight and argument. Many of the themes of Aristotelian philosophy – the nature of substance, the relation of form to matter, the relation of mind to body, the nature of human action, the role of virtues and actions in morality – have reappeared as issues in philosophical debates, and Aristotle's contributions to these debates have influenced the course of philosophical discussion.

In some ways, Aristotle has suffered from his success. At different times he has been regarded as the indisputable authority in astronomy, biology, logic and ethics; hence he has represented the traditional position against which reformers have revolted. If he is regarded neither as the indisputable authority nor as a repository of antiquated and discarded doctrines, his permanent philosophical value can be more justly appreciated.

ARITHMETIC, PHILOSOPHICAL ISSUES IN

The philosophy of arithmetic gains its special character from issues arising out of the status of the principle of mathematical induction. Indeed, it is just at the point where proof by induction enters that arithmetic stops being trivial. The propositions of elementary arithmetic – quantifier-free sentences such as '$7 + 5 = 12$' – can be decided mechanically: once we know the rules for calculating, it is hard to see what mathematical interest can remain. As soon as we allow sentences with one universal quantifier, however – sentences of the form '$(\forall x) f(x) = 0$' – we have no decision procedure either in principle or in practice, and can state some of the most profound and difficult problems in mathematics. (Goldbach's conjecture that every even number greater than 2 is the sum of two primes, formulated in 1742 and still unsolved, is of this type.)

It seems natural to regard as part of what we mean by natural numbers that they should obey the principle of induction. But this exhibits a form of circularity known as 'impredicativity': the statement of the principle involves quantification over properties of numbers, but to understand this quantification we must assume a prior grasp of the number concept, which it was our intention to define. It is nowadays a commonplace to draw a distinction between impredicative definitions, which are illegitimate, and impredicative specifications, which are not. The conclusion we should draw in this case is that the principle of induction on its own does not provide a non-circular route to an understanding of the natural number concept. We therefore need an independent argument. Four broad strategies have been attempted, which we shall consider in turn.

ARNAULD, ANTOINE (1612–94)

Antoine Arnauld, a leading theologian and Cartesian philosopher, was one of the most important and interesting figures of the seventeenth century. As the most prominent spokesperson and defender of the Jansenist community based at Port-Royal, almost all Arnauld's efforts were devoted to theological matters. But early on, with his largely constructive objections to Descartes' *Meditations* in 1641, he established a reputation as an analytically rigorous and insightful philosophical thinker. He went on to become perhaps Descartes' most faithful and vociferous defender. He found Cartesian metaphysics, particularly mind–body dualism, to be of great value for the Christian religion. In a celebrated debate with Nicolas Malebranche, Arnauld advanced something like a direct realist account of perceptual acquaintance by arguing that the representative ideas that mediate human knowledge and perception are not immaterial objects distinct from the mind's perceptions, but are just those perceptions themselves. His criticisms of Leibniz gave rise to another important debate. He also co-authored the so-called 'Port-Royal Logic', the most famous and successful

logic of the early modern period. The underlying motives in all Arnauld's philosophical writings were, however, theological, and his greatest concern was to safeguard God's omnipotence and to defend what he took to be the proper Catholic view on questions of grace and divine providence

ART, ABSTRACT

The use of the term 'abstract' as a category of visual art dates from the second decade of the twentieth century, when painters and sculptors had turned away from verisimilitude and launched such modes of abstraction as Cubism, Orphism, Futurism, Rayonism and Suprematism. Two subcategories may be distinguished: first, varieties of figurative representation that strongly schematize, and second, completely nonfigurative or nonobjective modes of design (in the widest sense of that term). Both stand opposed to classic representationalism (realism, naturalism, illusionism, mimeticism) understood as the commitment to a relatively full depiction of the subject matter and construed broadly enough to cover the traditional 'high art' canon through to Post-Impressionism. Analytic and Synthetic Cubism are model cases of the first subcategory while Mondrian's neoplasticism and Pollock's classic drip works are paradigms of the second. Though the effect was revolutionary, the positive motivations for this degree of abstraction in visual art were not wholly new. What was new was the elevation of previously subordinate aims to the front rank and the pursuit of certain principal aims in isolation from the full pictorial package. Thus abstract art variously celebrates structural and colour properties of objects, scenes and patterns; effects of motion, light and atmosphere; aspects of perceptual process, whether normal or expressively loaded; and forms expressing cosmic conceptions, visionary states or utopian ambitions. With a few exceptions (for example, the Futurists) the founders of abstract art were far from lucid or forthcoming about the significance of their work, and viewers have found successive waves of abstraction initially baffling and even offensive. But abstract art now forms a secure part of the 'high art' canon, though generally its appeal is less well understood than that of the classic modes of representation. Criticisms of abstract art have also become more lucid.

The chief philosophical issues affecting abstract art concern the definition of the term and the delineation of subordinate types; the relation between abstraction and other modes of avant-garde art that superficially resemble it; the magnitude of the artistic values so far achieved by the various forms; and finally the theoretical limits of significance attainable by abstraction as compared with the limits encountered in figurative art.

ART AND EMOTION

See Emotion in response to art

ART AND MORALITY

A complex set of questions is raised by an examination of the relationship between art and morality. First there is a set of empirical considerations about the effect that works of art have on us – one obviously contentious case is that of pornography. Many would argue that the artistic merits of a work are independent of any attitudes or actions it may lead us to adopt or perform. This claim does not survive scrutiny, however, though there is a distinction to be drawn between artistic value and the value of art as a whole. Though there are no coercive arguments to show that we have to take into account the moral qualities of works of art, it is in practice very difficult to ignore them, especially when the point of the work is insistently moral, or when the work is conspicuously depraved.

There is a long tradition, dating back to Plato, of regarding art with suspicion for its power over our emotions, and much of Western aesthetic theorizing has been a response to Plato's challenge. The longest-lasting defence justified art in terms of a combination of pleasure and instruction, though the two never hit it off as well as was hoped. In the early nineteenth century a new, more complex account of art was offered, notably by Hegel, in the form of a historicized view in which art is one of the modes by which we come to self-awareness; the emphasis altered from truth to an independently existing reality to truthfulness to our own natures, as we explore them by creating art. Taken into the social sphere, this became a doctrine of the importance of art as an agent of political consciousness, operating in subtle ways to undermine the view of reality imposed on us by the ideologies that hold us captive.

MICHAEL TANNER

ART AND TRUTH

Some things are true within the world of a literary work. It is true, in the world evoked by *Madame Bovary*, that Emma Roualt married Charles Bovary. Here, however, we are not concerned with truth *in* fiction but rather with what it is for a work of art to be true of, or true to, the actual world. Representational works represent states of affairs, or objects portrayed in a certain way. The concept of truth naturally gets a grip here, because we can ask whether the represented state of affairs actually exists in the world, or whether a represented object exists and really is the way it is represented to be, or whether a representation of a kind of thing offers a genuinely representative example of that kind. If so, we could call the work true, or true in the given respect.

A work will often get us to respond to what is portrayed in a way similar to what our response would have been to the real thing – we are moved to fear and pity by objects we know are merely fictions. But a work could also *portray* characters responding in certain ways to the imaginary situations it conjures, often with the implication that the response is a likely human emotional or practical response to that situation, or a response to be expected of a character of the given type, and we could reasonably call the work true if we believed the portrayed reaction was a likely one.

Arguably, if we judge a work to be in some respect true to life, we must already have known that life was like that in order to make the judgment. But, interestingly, works of art appear to be able to portray situations that we have not experienced, in which the portrayal seems to warrant our saying that the work has shown (that is, taught) us a likely or plausible unfolding of the portrayed situation, or shown us what it would have been like to experience the situation. It is also said, especially of narrative fiction, that, because of its power to show us what various alternative imaginary situations would be like, it can enlighten us about how we ought to live.

So we may consider how a work of art might be a vehicle of truths about the actual world. This gives rise to a further question – sometimes called the problem of belief – of whether the value of a work of art *as* a piece of art is related to its truth. If a work implies or suggests that something is the case, ought I to value it more highly as art if I accept what it implies as the truth? Alternatively, should I take it as an aesthetic shortcoming if I do not?

PAUL TAYLOR

ART CRITICISM

To criticize a work of art is to make a judgment of its overall merit or demerit and to support that judgment by reference to features it possesses. This activity is of great antiquity; we find Aristotle, for example, relating the excellence of Sophocles' *Oedipus Rex* to the excellence of its plot construction. Criticism became a topic in philosophy because reflection on the kinds of things said by critics generated various perplexities and in some cases encouraged a general scepticism about the possibility of criticism. Two general and related problems in particular have taxed philosophers. The first is the question of whether criticism is a rational activity, that is to say, whether critics can give reasons for their judgments that would persuade potential dissenters of the rightness of those judgments. The second, a matter to which Kant and Hume made notable contributions, is the problem of the objectivity of critical judgments, it being widely believed that critical appraisals are wholly subjective or just 'a matter of taste'. Arguments that use deductive or inductive reasoning to demonstrate the possibility of proofs of critical judgments are generally agreed to have failed. Another approach redescribes the critic altogether, not as someone who uses argument to prove their judgments to an audience, but as someone who aims to help the audience perceive features of the work of art and understand their role in the work.

COLIN LYAS

ART, DEFINITION OF

Many of the earliest definitions of art were probably intended to emphasize salient or important features for an audience already familiar with the concept, rather than to analyse the essence possessed by all art works and only by them. Indeed, it has been argued that art could not be defined any more rigorously, since no immutable essence is observable in its instances. But, on the one hand, this view faces difficulties in explaining the unity of the concept – similarities between them, for example, are insufficient to distinguish works of art from other things. And, on the other, it overlooks the attractive possibility that art is to be defined in terms of a relation between the activities of artists, the products that result and the audiences that receive them.

Two types of definition have come to prominence since the 1970s: the functional and procedural. The former regards something as art only if it

serves the function for which we have art, usually said to be that of providing aesthetic experience. The latter regards something as art only if it has been baptized as such through an agent's application of the appropriate procedures. In the version where the agent takes their authority from their location within an informal institution, the 'artworld', proceduralism is known as the institutional theory. These definitional strategies are opposed in practice, if not in theory, because the relevant procedures are sometimes used apart from, or to oppose, the alleged function of art; obviously these theories disagree then about whether the outcome is art.

To take account of art's historically changing character a definition might take a recursive form, holding that something is art if it stands in an appropriate relation to previous art works: it is the location of an item within accepted art-making traditions that makes it a work of art. Theories developed in the 1980s have often taken this form. They variously see the crucial relation between the piece and the corpus of accepted works as, for example, a matter of the manner in which it is intended to be regarded, or of a shared style, or of its being forged by a particular kind of narrative.

STEPHEN DAVIES

ART, FORMALISM IN

See Formalism in art

ART, UNDERSTANDING OF

Art engages the understanding in many ways. Thus, confronted with an allegorical painting such as Van Eyk's *The Marriage of Arnolfini*, one might want to understand the significance of the objects it depicts. Similarly, confronted with an obscure poem, such as Eliot's *The Waste Land*, one might seek to understand what it means. Sometimes, too, we claim not to understand a work of art, a piece of music, say, when we are unable to derive enjoyment from it because we cannot see how it is organized or hangs together. Sometimes what challenges the understanding goes deeper, as when we ask why some things, including such notorious productions of the avant garde as the urinal exhibited by Marcel Duchamp, are called art at all. Some have also claimed that to understand a work of art we must understand its context. Sometimes the context referred to is that of the particular problems and aims of the individual artist in a certain tradition, as when the church of St Martin-in-the-Fields is understood as a contribution by its architect to the vexing problem of combining a tower with a classical façade. Sometimes the context is social, as when some Marxists argue that works of art can best be understood as reflections of the more or less inadequate economic organizations of the societies that gave rise to them. The understanding of art becomes a philosophical problem because, first, it is sometimes thought that one of the central tasks of interpretation is to understand the meaning of a work. However, recent writers, notably Derrida, query the notion of the meaning of a work as something to be definitively deciphered, and offer the alternative view of interpretation as an unending play with the infinitely varied meanings of the text. Second, a controversial issue has been the extent to which the judgment of works of art can be divorced from an understanding of the circumstances, both individual and cultural, of their making. Thus Clive Bell argued that to appreciate a work of art we need nothing more than a knowledge of its colours, shapes and spatial arrangements. Others, ranging from Wittgenstein to Marxists, have for a variety of different reasons argued that a work of art cannot be properly understood and appreciated without some understanding of its relation to the context of its creation, a view famously characterized by Beardsley and Wimsatt as the 'genetic fallacy'.

COLIN LYAS

ART, VALUE OF

Art has as many kinds of value as there are points of view from which it can be evaluated. Moreover, the benefits of art vary with the role of the participant, for there are benefits that are specific to the creation, the performance and the mere appreciation of art. But in the philosophy of art one value is basic, namely the distinctive value of a work of art, its value *as* a work of art, which can be called its 'artistic value'. This value is intrinsic to a work in that it is determined by the intrinsic, rather than the instrumental, value of an informed experience of it, an experience of it in which it is understood. Artistic value is a matter of degree, but it is not a measurable quantity, and whether one work is better than another may be an indeterminate issue. A judgment about a work's artistic value claims validity, rightly or wrongly, not merely for the person who makes the judgment but for everyone. Both David Hume and Immanuel Kant tried to show how such a claim could be well-founded, but their attempts are usually considered failures, and there is no accepted solution to the problem they addressed. Many philosophers have been concerned with the relation between artistic value and other values. The most famous attack on art, founded on

its supposed relation to other values, was made by Plato, who claimed that nearly all art has undesirable social consequences and so should be excluded from a decent society. Plato overlooked many possibilities, however, and the question of art's beneficial or harmful influence is a much more complex issue than he recognized.

MALCOLM BUDD

ART WORKS, ONTOLOGY OF

In trying to decide what kinds of thing art works are, the most natural starting point is the hypothesis that they are physical objects. This is plausible only for certain works, such as paintings and sculptures; in such cases we say that the work is a certain marked canvas or piece of stone. Even for these apparently favourable cases, though, there is a metaphysical objection to this proposal: that works and the physical objects identified with them do not possess the same properties and so cannot be identical. There is also an aesthetic objection: that the plausibility of the thesis for painting and sculpture rests on the false view that the authentic object made by the artist possesses aesthetically relevant features which no copy could possibly exemplify. Once it is acknowledged that paintings and sculptures are, in principle, reproducible in the way that novels and musical scores are, the motivation for thinking of the authentic canvas or stone as the work itself collapses.

For literary and musical works, the standard view is that they are structures: structures of word-types in the literary case and of sound-types in the musical case. This structuralist view is opposed by contextualism, which asserts that the identity conditions for works must take into account historical features involving their origin and modes of production. Contextualists claim that works with the same structure might have different historical features and ought, therefore, to count as distinct works.

Nelson Goodman has proposed that we divide works into autographic and allographic kinds; for autographic works, such as paintings, genuineness is determined partly by history of production: for allographic works, such as novels, it is determined in some other way. Our examination of the hypothesis that certain works are physical objects and our discussion of the structuralist/contextualist controversy will indicate grounds for thinking that Goodman's distinction does not provide an acceptable categorization of works.

A wholly successful ontology of art works would tell us what things are art works and what things are not; failing that, it would give us identity conditions for them, enabling us to say under what conditions this work and that are the same work. Since the complexity of the issues to be discussed quickly ramifies, it will be appropriate after a certain point to consider only the question of identity conditions. For simplicity, this entry concentrates on works of art that exemplify written literature, scored music and the plastic and pictorial arts.

ARTIFICIAL INTELLIGENCE

Artificial intelligence (AI) tries to make computer systems (of various kinds) do what minds can do: interpreting a photograph as depicting a face; offering medical diagnoses; using and translating language; learning to do better next time.

AI has two main aims. One is technological: to build useful tools, which can help humans in activities of various kinds, or perform the activities for them. The other is psychological: to help us understand human (and animal) minds, or even intelligence in general.

Computational psychology uses AI concepts and AI methods in formulating and testing its theories. Mental structures and processes are described in computational terms. Usually, the theories are clarified, and their predictions tested, by running them on a computer program. Whether people perform the equivalent task in the same way is another question, which psychological experiments may help to answer. AI has shown that the human mind is more complex than psychologists had previously assumed, and that introspectively 'simple' achievements – many shared with animals – are even more difficult to mimic artificially than are 'higher' functions such as logic and mathematics.

There are deep theoretical disputes within AI about how best to model intelligence. Classical (symbolic) AI programs consist of formal rules for manipulating formal symbols; these are carried out sequentially, one after the other. Connectionist systems, also called neural networks, perform many simple processes in parallel (simultaneously); most work in a way described not by lists of rules, but by differential equations. Hybrid systems combine aspects of classical and connectionist AI. More recent approaches seek to construct adaptive autonomous agents, whose behaviour is self-directed rather than imposed from outside and which adjust to environmental conditions. Situated robotics builds robots that react directly to environmental cues, instead of following complex internal plans as classical robots do. The programs, neural

networks and robots of evolutionary AI are produced not by detailed human design, but by automatic evolution (variation and selection). Artificial life studies the emergence of order and adaptive behaviour in general and is closely related to AI.

Philosophical problems central to AI include the following. Can classical or connectionist AI explain conceptualization and thinking? Can meaning be explained by AI? What sorts of mental representations are there (if any)? Can computers, or non-linguistic animals, have beliefs and desires? Could AI explain consciousness? Might intelligence be better explained by less intellectualistic approaches, based on the model of skills and know-how rather than explicit representation?

ARTISTIC EXPRESSION

Many kinds of psychological state can be expressed in or by works of art. But it is the artistic expression of emotion that has figured most prominently in philosophical discussions of art. Emotion is expressed in pictorial, literary and other representational works of art by the characters who are depicted or in other ways presented in the works. We often identify the emotions of such characters in much the same way as we ordinarily identify the emotions of others, but we might also have special knowledge of a character's emotional state, through direct access to their thoughts, for instance.

A central case of the expression of emotion by works of art is the expression of emotion by a purely musical work. What is the source of the emotion expressed by a piece of music? While art engages its audience, often calling forth an emotional response, its expressiveness does not consist in this power. It is not because an art work tends to make us feel sad, for instance, that we call it sad; rather, we react as we do because sadness is present in it. And while artists usually contrive the expressiveness of their art works, sometimes expressing their own emotions in doing so, their success in the former activity does not depend on their doing the latter. Moreover, the expressiveness achieved has an immediacy and transparency, like that of genuine tears, apparently at odds with this sophisticated, controlled form of self-expression. It is because art presents emotion with simple directness that it can be a vehicle for self-expression, not vice versa. But if emotions are the experiences of sentient beings, to whom do those expressed in art belong if not to the artist or audience? Perhaps they are those of a fictional persona. We may imagine personae who undergo the emotions expressed in art, but it is not plain that we must do so to become aware of that expressiveness, for it is arguable that art works present appearances of emotions, as do masks, willow trees and the like, rather than outward signs of occurrent feelings. Expressiveness is valuable because it helps us to understand emotions in general while contributing to the formation of an aesthetically satisfying whole.

ARTIST'S INTENTION

W.K. Wimsatt and Monroe C. Beardsley's famous paper 'The Intentional Fallacy' (1946) began one of the central debates in aesthetics and literary theory of the last half-century. By describing as a fallacy the belief that critics should take into account the author's intentions when interpreting or evaluating a piece of literature, they were rejecting an entrenched assumption of traditional criticism – and a natural one, since we normally take it for granted that understanding actions, including acts of speech and writing, requires a grasp of the intentions of the agent. But they were expressing an idea that has been greatly influential; it was a central claim of the 'new criticism', while the marginalization of the author is also a marked feature of structuralist and poststructuralist literary theory. Most of the debate over the artist's intentions – 'artist' here being used as a general word for writer, composer, painter, and so on – has centred on their relevance for *interpreting* art works. More particularly, the question has been whether *external* evidence about the artist's intentions – evidence not presented by the work itself – is relevant to determining the work's meaning.

ASCETICISM

The term 'asceticism' is derived from the Greek word, *askēsis*, which referred originally to the sort of exercise, practice or training in which athletes engage. Asceticism may be characterized as a voluntary, sustained and systematic programme of self-discipline and self-denial in which immediate sensual gratifications are renounced in order to attain some valued spiritual or mental state. Ascetic practices are to be found in all the major religious traditions of the world, yet they have often been criticized by philosophers. Some argue that the

religious doctrines that they presuppose are false or unreasonable. Others contend that they express a preference for pain that humans cannot consistently act upon.

ATHEISM

Atheism is the position that affirms the nonexistence of God. It proposes positive disbelief rather than mere suspension of belief. Since many different gods have been objects of belief, one might be an atheist with respect to one god while believing in the existence of some other god. In the religions of the West – Judaism, Christianity and Islam – the dominant idea of God is of a purely spiritual, supernatural being who is the perfectly good, all-powerful, all-knowing creator of everything other than himself. As used here, in the narrow sense of the term an atheist is anyone who disbelieves in the existence of this being, while in the broader sense an atheist is someone who denies the existence of any sort of divine reality. The justification of atheism in the narrow sense requires showing that the traditional arguments for the existence of God are inadequate as well as providing some positive reasons for thinking that there is no such being. Atheists have criticized the traditional arguments for belief and have tried to justify positive disbelief by arguing that the properties ascribed to this being are incoherent, and that the amount and severity of evils in the world make it quite likely that there is no such all-powerful, perfectly good being in control.

ATOMISM, ANCIENT

Ancient Greek atomism, starting with Leucippus and Democritus in the fifth century BC, arose as a response to problems of the continuum raised by Eleatic philosophers. In time a distinction emerged, especially in Epicurean atomism (early third century BC), between physically indivisible particles called 'atoms' and absolutely indivisible or 'partless' magnitudes.

ATOMISM IN THE SEVENTEENTH CENTURY

See Gassendi, ierrev

AUGUSTINE (AD 354–430)

Augustine was the first of the great Christian philosophers. For well over eight centuries following his death, in fact until the ascendancy of Thomas Aquinas at the end of the thirteenth century, he was also the single most influential Christian philosopher. As a theologian and Church Father, Augustine was the person who did the most to define Christian heresy and so, by implication, to formulate Christian orthodoxy. Of the three most prominent heresies defined by Augustine – Donatism, Pelagianism and Manicheism – the latter two also have especially important philosophical implications. In rejecting Pelagianism and its thesis of human perfectibility, Augustine rejected one form of the principle, often associated with Kant, that 'ought' implies 'can', and in rejecting Manicheism, with its doctrine that good and evil are equally basic metaphysical realities, Augustine rejected one solution to the philosophical problem of evil.

The *Categories* may have been the only work of Aristotle that Augustine actually read. Plato he knew somewhat better. He seems to have been familiar with several Platonic dialogues and he clearly felt a special affinity for Plato and the Platonists, which is particularly evident in *De civitate Dei* (The City of God) and *De vera religione* (On True Religion). Although he could be said to have responded to classical Greek philosophy in consequential ways, it must be added that what he responded to had been filtered through Neoplatonism, Hellenistic scepticism and Stoicism. It was principally through the writings of Cicero that Augustine became schooled in the opinions of his philosophical predecessors, and it was through the works of the Neoplatonists that he developed his deep appreciation for Plato.

Augustine's philosophy thus draws significantly on the philosophy of late antiquity as well as on Christian revelation. Its originality lies partly in its synthesis of Greek and Christian thought, and partly in its development of a novel ego-centred approach to philosophy that anticipates modern thought, especially as exemplified in the philosophy of Descartes. In his *De trinitate* (The Trinity) and *De civitate Dei*, Augustine presents a line of thinking that foreshadows Descartes' famous *cogito, ergo sum*. Through his *Confessionum libri tredecim* (Confessions, more usually known as *Confessiones*), the first significant autobiography in Western literature, and also through his *Soliloquia* (Soliloquies), which is a dialogue between himself and Reason, Augustine introduced a first-person perspective to Western philosophy.

Early in his career, Augustine found himself attracted to philosophical scepticism. In his earliest extant work he offers his most extensive response to the main sceptical arguments of his day, including those that raise the possibility one might only be dreaming. His later responses to scepticism, though less extensive, are better focused; they concentrate on the self-knowledge he considers directly available to each knowing subject, including the knowledge that one exists. Taking the first-person perspective one can also develop, he tries to show, in his *De trinitate*, a convincing argument for mind–body dualism. But supposing, as he does, that each of us knows from our own case what a mind is raises, as Augustine is perhaps the first philosopher to realize, a problem about how one can ever know that there are minds in addition to one's own.

Augustine's account of language and meaning influenced the development of 'terminist' logic in the high middle ages. His thoughts on language acquisition in *Confessiones* provide a foil for Wittgenstein in the latter's *Philosophical Investigations.* Yet, some of Augustine's own reflections on ostensive definition in his dialogue *De magistro* (The Teacher) anticipate Wittgenstein's own views on language learning.

Augustine develops what is described as an 'active' theory of sense perception, according to which rays of vision touch objects whose consequent action on the body is 'noticed' by the mind or soul. Although his ideas on sense perception are interesting, his most influential epistemological conception is certainly his 'theory of illumination'. Instead of supposing that what we know can be abstracted from sensible particulars that instantiate such knowledge, he insists that our mind is so constituted as to see 'intelligible realities' directly by an inner illumination.

The modern concept of the will is often said to originate with Augustine. Certainly the idea of will is central to his philosophy of mind, as well as to his account of sin and the origin of evil. Strikingly, he uses psychological 'trinities', including the trinity of memory, understanding and will, to illuminate the doctrine of the Divine Trinity, where there is also a baffling unity in plurality. The theological warrant for this analogy Augustine finds in the biblical idea that God created human beings, and specifically the human mind, in his own image.

Augustine's attempts to achieve a philosophical understanding of theology and religious belief set the framework for much later medieval and early modern philosophy. On the issue of how reason should bear on religious faith, Augustine develops the idea that reason should work out an understanding of what we must first accept on faith. Yet he also displays a keen sensitivity to those issues most likely to challenge one's religious faith. Prominent among his concerns is the philosophical problem of evil, to which he offers what has proved to be perhaps the most influential type of solution.

Particularly striking is Augustine's virtually lifelong preoccupation with human freedom and how the fact that human beings are free to make their own choices can be reconciled with the Christian doctrines of God's foreknowledge, predestination and grace. Almost every important medieval philosopher in the Christian West would later contribute to the continuing effort to achieve a satisfactory reconciliation of these issues. It is significant that Leibniz, who gave the problem of freedom, foreknowledge, predestination and grace one of its most sophisticated treatments, also gave much of his philosophical attention to the equally Augustinian problem of evil.

Although Augustine did present an argument for the existence of God, it is his understanding of the divine attributes, and especially his insistence on divine 'simplicity', that is, on the idea that God is not distinct from his attributes, that has been especially influential on later thinkers. Also influential are his various attempts to understand the created world. Augustine made several important efforts, perhaps most notably in the last books of his *Confessiones* and in his *De genesi ad litteram* (The Literal Meaning of Genesis) to give a philosophically sophisticated account of the creation story in the biblical book of Genesis. His contrast between God's eternity and human temporality set the stage for later medieval and modern discussions of these issues, and his discussion of the nature of time in Book XI of his *Confessiones* is sometimes taken to epitomize philosophy.

Augustine's descriptions of mystical experience are among the most eloquent in Western literature; they belong among the classic texts of mysticism. However, Augustine's attempts to understand ritual are perhaps more remarkable for the directness with which he identifies and confronts difficult issues than for the success of his efforts to solve them. Those efforts seem to be hobbled by his version of mind–body dualism.

Augustine is a thoroughgoing intentionalist in ethics. This feature of his thought, as well as his unflinching insistence that one can do what one knows one ought not to be doing, mark him off from ethicists of the classical Greek period. Yet Augustine also preserves in his own thinking important strands of ancient Greek thought. Thus, for example, his development of the doctrine of the Christian virtues includes an echo of Plato's idea of the unity of the virtues. His insistence that 'ought' does not, in any straightforward way, imply 'can', distinguishes him, not only from his contemporary

Pelagius, whom he helped brand as a Christian heretic, but also from most modern ethicists as well.

The philosophy of history Augustine develops in *De civitate Dei* initiates a branch of philosophy that came into full flower in the nineteenth century. Also in that same work Augustine makes an influential contribution to what has come to be called 'just war theory', an applied ethical theory that has continued to develop even into the latter half of the twentieth century.

GARETH B. MATTHEWS

AUSTIN, JOHN (1790–1859)

Although written in the early nineteenth century, Austin's is probably the most coherent and sustained account of the theory of legal positivism. The complex relationships between legal positivism and the concepts of morality and politics are explored by him but are often neglected or misunderstood in modern commentaries.

ROBERT N. MOLES

AUSTIN, JOHN LANGSHAW (1911–60)

J.L. Austin was a leading figure in analytic philosophy in the fifteen years following the Second World War. He developed a method of close examination of nonphilosophical language designed to illuminate the distinctions we make in ordinary life. Professional philosophers tended to obscure these important and subtle distinctions with undesirable jargon which was too far removed from everyday usage. Austin thought that a problem should therefore be tackled by an examination of the way in which its vocabulary is used in ordinary situations. Such an approach would then expose the misuses of language on which many philosophical claims were based.

In 'Other Minds' (1946), Austin attacked the simplistic division of utterances into the 'descriptive' and 'evaluative' using his notion of a performatory, or performative utterances. His notion was that certain utterances, in the appropriate circumstances, are neither descriptive nor evaluative, but count as actions. Thus to say 'I promise' is to make a promise, not to talk about one. Later, he was to develop the concepts of locutionary force (what an utterance says or refers to), illocutionary force (what is intended by saying it) and perlocutionary force (what effects it has on others).

J.O. URMSON

AUTHORITY

The notion of authority has two main senses: expertise and the right to rule. To have authority in matters of belief (to be 'an authority') is to have *theoretical authority*; to have authority over action (to be 'in authority') is to have *practical authority*. Both senses involve the subordination of an individual's judgment or will to that of another person in a way that is binding, independent of the particular content of what that person says or requires. If a person's authority is recognized then it is effective or *de facto* authority; if it is justified then it is *de jure* authority. The latter is the primary notion, for *de jure* authority is what *de facto* authorities claim and what they are believed to have. Authority thus differs from effective power, but also from justified power, which may involve no subordination of judgment. In many cases, however, practical authority is justified only if it is also effective.

Political authority involves a claim to the obedience of its subjects. Attempts to justify it have always been at the core of political philosophy. These include both instrumental arguments appealing to the expertise of rulers or to their capacity to promote social cooperation, and non-instrumental arguments resting on ideas such as consent or communal feeling. Whether any of these succeed in justifying the comprehensive authority that modern states claim is greatly disputed.

LESLIE GREEN

AUTONOMY, ETHICAL

The core idea of autonomy is that of sovereignty over oneself, self-governance or self-determination: an agent or political entity is autonomous if it is self-governing or self-determining. The ancient Greeks applied the term to city-states. In the modern period, the concept was extended to persons, in particular by Kant, who gave autonomy a central place in philosophical discourse. Kant argued for the autonomy of rational agents by arguing that moral principles, which authoritatively limit how we may act, originate in the exercise of reason. They are thus laws that we give to ourselves, and Kant thought that rational agents are bound only to self-given laws. Much contemporary discussion has focused on the somewhat different topic of personal autonomy, and autonomy continues to be an

important value in contemporary liberalism and in ethical theory.

It is important to distinguish different senses of autonomy because of variation in how the concept is used. Self-governance or self-determination appears to require some control over the desires and values that move one to action, and some such control is provided by the capacity to subject them to rational scrutiny. Thus, autonomy is often understood as the capacity to critically assess one's basic desires and values, and to act on those that one endorses on reflection. In other contexts, autonomy is understood as a right, for example as the right to act on one's own judgment about matters affecting one's life, without interference by others. The term is also sometimes used in connection with ethics itself, to refer to the thesis that ethical claims cannot be reduced to nonethical claims.

AYER, ALFRED JULES (1910–89)

A.J. Ayer made his name as a philosopher with the publication of *Language, Truth and Logic* in 1936, a book which established him as the leading English representative of logical positivism, a doctrine put forward by a group of philosophers known as members of the Vienna Circle. The major thesis of logical positivism defended by Ayer was that all literally meaningful propositions were either analytic (true or false in virtue of the meaning of the proposition alone) or verifiable by experience. This, the verificationist theory of meaning, was used by Ayer to deny the literal significance of any metaphysical propositions, including those that affirmed or denied the existence of God. Statements about physical objects were said to be translatable into sentences about our sensory experiences (the doctrine known as phenomenalism). Ayer further claimed that the propositions of logic and mathematics were analytic truths and that there was no natural necessity, necessity being a purely logical notion. Finally the assertion of an ethical proposition, such as 'Stealing is wrong', was analysed as an expression of emotion or attitude to an action, in this case the expression of a negative attitude to the act of stealing.

During the rest of his philosophical career Ayer remained faithful to most of these theses, but came to reject his early phenomenalism in favour of a sophisticated realism about physical objects. This still gives priority to our experiences, now called percepts, but the existence of physical objects is postulated to explain the coherence and consistency of our percepts. Ayer continued to deny that there were any natural necessities, analysing causation as consisting in law-like regularities. He used this analysis to defend a compatibilist position about free action, claiming that a free action is to be contrasted with one done under constraint or compulsion. Causation involves mere regularity, and so neither constrains nor compels.

GRAHAM MACDONALD

B

BACHELARD, GASTON (1884–1962)

One indication of the originality of Bachelard's work is that he was famous for his writings both in the philosophy of science and on the poetic imagination. His work demonstrates his belief that the life of the masculine, work-day consciousness (animus), striving towards scientific objectivity through reasoning and the rectification of concepts, must be complemented by the life of a nocturnal, feminine consciousness (anima), seeking an expanded poetic subjectivity, as, in reverie, it creates the imaginary.

In common with other scientist-philosophers writing in the first half of the twentieth century, Bachelard reflected on the upheavals wrought by the introduction of relativity theory and quantum mechanics. The views at which he arrived were, however, unlike those of his contemporaries; he argued that the new science required a new, non-Cartesian epistemology, one which accommodated discontinuities (epistemological breaks) in the development of science. It was only after he had established himself as one of France's leading philosophers of science, by succeeding Abel Rey in the chair of history and philosophy of science at the Sorbonne, that Bachelard began to publish works on the poetic imagination. Here his trenchantly anti-theoretical stance was provocative. He rejected the role of literary critic and criticized literary criticism, focusing instead on reading images and on the creative imagination.

MARY TILES

BACON, FRANCIS (1561–1626)

Introduction

Along with Descartes, Bacon was the most original and most profound of the intellectual reformers of the sixteenth and seventeenth centuries. He had little respect for the work of his predecessors, which he saw as having been vitiated by a misplaced reverence for authority, and a consequent neglect of experience. Bacon's dream was one of power over nature, based on experiment, embodied in appropriate institutions and used for the amelioration of human life; this could be achieved only if the rational speculations of philosophers were united with the craft-skills employed in the practical arts.

The route to success lay in a new method, one based not on deductive logic or mathematics, but on eliminative induction. This method would draw on data extracted from extensive and elaborately constructed natural histories. Unlike the old induction by simple enumeration of the logic textbooks, it would be able to make use of negative as well as positive instances, allowing conclusions to be established with certainty, and thus enabling a firm and lasting structure of knowledge to be built.

Bacon never completed his project, and even the account of the new method in the *Novum Organum* (1620) remained unfinished. His writings nevertheless had an immense influence on later seventeenth-century thinkers, above all in stimulating the belief that natural philosophy ought to be founded on a systematic programme of experiment. Perhaps his most enduring legacy, however, has been the modern concept of technology – the union of rational theory and empirical practice – and its application to human welfare.

1 Life

Francis Bacon was born into the political elite of Elizabethan England. His father, Nicholas, was Lord Keeper; his mother, Anne, sister-in-law to Lord Burghley, the Lord Treasurer. Much of Bacon's

career and even some aspects of his philosophy can best be understood as resulting from an upbringing which made him familiar with the exercise of power, and the wealth that came with it. His perspective is always that of an insider, but of one who experienced considerable difficulty in establishing his own position as such.

In 1573 Bacon was admitted to Trinity College, Cambridge. In later recollection at least, he found little to admire in the Aristotelian philosophy to which he was introduced, and still less in the writings of such authors as Peter Ramus, who were becoming fashionable alternatives (see ARISTOTLE; RAMUS, P.). As was usual with undergraduates of his social rank, he did not take a degree. In 1576 he returned to London to train as a barrister at Gray's Inn, an institution with which he was to maintain a much more enduring connection. His father died in 1579, leaving him with only a modest inheritance. Throughout his life Bacon spent freely and lived beyond his income; quite apart from considerable personal ambition, much of his pursuit of office can be seen as an attempt to repair chronic indebtedness.

Though he was elected to successive parliaments from 1581 onwards, Bacon's career did not flourish under Queen Elizabeth, who recognized his abilities but seems to have found his personality unappealing. Burghley was more concerned to advance the career of his own son Robert, later Earl of Salisbury, and Bacon attached himself to Elizabeth's last favourite, the brilliant but insubstantial Earl of Essex. Essex's attempt in 1601 to restore his fortunes by staging an insurrection proved a complete fiasco, and made him liable to prosecution for treason. Bacon adroitly changed sides and prosecuted his former patron with a skill and vigour which provided ample confirmation both of his remarkable talents and of a fundamental coldness of character.

The accession of James I in 1603 presented the prospect – initially unfulfilled – of professional advancement. Bacon was knighted soon after the King's arrival in London, but he had to wait until 1607 before being given his first important office, that of Solicitor General. It was only after the death of Salisbury in 1612 that promotion became truly rapid: in 1613 he was appointed Attorney General, in 1617 Lord Keeper, and in 1618 Lord Chancellor. This last office brought admission to the peerage, first as Baron Verulam (1618) and then as Viscount St Albans (1621).

Bacon's fall was precipitous and catastrophic, though not entirely unpredictable. He had supplemented the income from his office by taking payments from those whose cases he heard, and though this was far from unprecedented it did make him vulnerable to attack. He was also important enough to be a substantial sacrifice to an angry House of Commons, without being so close to James that he could not be dispensed with. At the beginning of May 1621 Bacon was deprived of office, imprisoned – albeit for only a few days – in the Tower of London, fined £40,000, barred from court and prevented from taking his place in the House of Lords.

Despite his best efforts, Bacon never returned to favour. He spent his last five years in retirement, writing incessantly – at first with the hope of regaining office, or at least influence, and then merely to leave a testament to posterity. He died on Easter Day 1626, according to John Aubrey (who had the story from Hobbes) from a cold contracted after an experiment of stuffing a chicken with snow. As has often been remarked, it was a fitting end for so fervent an advocate of experimental science.

2 Works

During the first two decades of his adult life Bacon wrote little, or at least little that survives; it was however in this period that his outlook and basic ideas were formed – certainly by the early 1590s, and probably earlier still; in 1625 he mentioned to a correspondent that forty years earlier he had advocated the reform of learning in a work (now lost) entitled *Temporis Partus Maximus* (The Greatest Birth of Time). The direction of Bacon's interests is apparent in a letter of 1592, written to Lord Burghley, in which he (rather disingenuously) disclaimed any political ambition while simultaneously indicating the scope of his intellectual projects:

> I confess that I have as vast contemplative ends, as I have moderate civil ends: for I have taken all knowledge to be my province; and if I could purge it of two sorts of rovers, whereof the one with frivolous disputations, confutations, and verbosities, the other with blind experiments and auricular traditions and impostures, hath committed so many spoils, I hope I should bring in industrious observations, grounded conclusions, and profitable inventions and discoveries; the best state of that province.
>
> (*The Works of Francis Bacon* 1857–74 VIII: 109)

These themes, developed and articulated, were to preoccupy Bacon for the remainder of his life. No echo of them was however to appear in print for several years. Apart from some political tracts, the only one of Bacon's writings to be published during Elizabeth's reign was the first edition of the *Essays* (1597); the only portion of this volume of any

philosophical significance is a short tract on 'The Colours of Good and Evil', which provides early evidence of Bacon's lifelong interest in fallacies and the pathology of the intellect.

The accession of James I stimulated a new burst of literary activity, of which the most visible result was *The Advancement of Learning* (1605), dedicated to the King and evidently written in the (unfulfilled) hope of munificent royal patronage. This was not the only project to have occupied Bacon's attention during the first years of the new reign. A large number of fragmentary treatises have survived, some in English, some in Latin. Several have strange, enigmatic titles: *Temporis Partus Masculus* (The Masculine Birth of Time), *Valerius Terminus of the Interpretation of Nature with the Annotations of Hermes Stella*, *Filum Labyrinthi* (The Thread of the Labyrinth). Others are more prosaic: *Redargutio Philosophiarum* (The Refutation of Philosophies), *Cogitata et Visa de Interpretatione Naturae* (Thoughts and Conclusions on the Interpretation of Nature). The diversity of the literary form displayed by these works is as striking as their unity of message: Bacon knew at least in outline what he wanted to say, but was undecided as to the most appropriate form in which to say it.

The last of these fragments probably dates from around 1608. For the next twelve years Bacon was increasingly busy with his official duties, and much of the time that remained was spent drafting and redrafting the *Novum Organum*. He did however find time to publish a second expanded edition of the *Essays* (1612) and one new work, *De Sapientia Veterum* (On the Wisdom of the Ancients) (1609), an interpretation of ancient myths as allegories of political and physical doctrine. The same pattern of thought can be found in the unpublished *De Principiis atque Originibus* (On Principles and Origins) (*c.*1610–12?), which also shows the considerable influence of Bernardino Telesio on Bacon's physical doctrines, as do two other works written around 1612, *Descriptio Globi Intellectualis* (A Description of the Intellectual Globe) and *Thema Coeli* (Theory of the Heavens), both left unfinished and unpublished.

The first instalment of Bacon's chief work, the *Instauratio Magna*, was eventually published with appropriate magnificence in 1620, when Bacon was at the pinnacle of his success. The whole work was to contain six parts, but all that appeared at this stage were a general preface, an outline of the project as a whole (the *Distributio Operis*), an incomplete section of the second part (the *Novum Organum*), and a short *Parasceve ad Historiam Naturalem et Experimentalem* (Preparative towards a Natural and Experimental History).

In the years that followed, Bacon went some way towards filling the lacunae in his original plan. The missing first part was supplied in 1623 by *De Dignitate et Augmentis Scientarum*, a revised and greatly extended translation of *The Advancement of Learning*. Despite its evident incompleteness, nothing more was added to the *Novum Organum*; most of Bacon's efforts went into the natural histories intended to fill Part III, which he rather optimistically planned to produce at the rate of one per month. In the event only two were published before his death: on winds (*Historia Ventorum* 1622) and on life and death (*Historia Vitae et Mortis* 1623), although a work on the condensation and rarefaction of materials (*Historia Densi et Rari*) was also completed in 1623. Bacon's executors ignored this – it eventually appeared in 1658 – but did publish the *Sylva Sylvarum* (1627), a natural history in English filled with some very dubious material, which proved very popular during the remainder of the century, but which provided much material for Bacon's nineteenth-century detractors.

The final three parts of *Instauratio Magna* were never written apart from short prefaces to parts four and five. The first of these, *Ladder of the Intellect*, was to contain actual examples of the new method in operation – something closer to perfection than the mere sketches provided in the *Novum Organum*. Part V, *Forerunners, or Anticipations of the Second Philosophy*, would, by contrast, exhibit discoveries made independently of the method, by the ordinary workings of the understanding. The content of the final part, the *Second Philosophy or Active Science*, can only be conjectured; one may suspect that Bacon himself had no very precise idea of what it would contain.

Perhaps the best picture of Bacon's final vision can be found in a work of a very different kind, published in the volume containing the *Sylva Sylvarum* but of uncertain date. *The New Atlantis* is an account of an imaginary voyage to an island in the Pacific Ocean, and of the scientific institution, Salomon's House, found there. Like most utopian narratives, this is deeply revealing of its author and provides the fullest picture we have of Bacon's vision of a reformed, active science, and of the kind of institution that he saw as necessary to its flourishing. It also had a profound influence both on the millennialist, visionary Baconianism of the 1640s and on the founders and early practice of the Royal Society.

3 The division of learning

The Advancement of Learning contains two books, the first on the dignity of learning and the reasons for the discredit with which it was often regarded, the second and much longer on the classification of its various branches; in the 1623 translation this latter was expanded further, and divided into eight books.

The primary division of the branches of learning reflects the faculties of the human mind: history corresponds to memory, poetry to imagination, and philosophy to reason. Philosophy itself has three subdivisions: divine philosophy or natural theology, natural philosophy, and human philosophy, this last including the doctrine of the soul, logic, rhetoric, ethics and politics). Metaphysics is a branch of natural philosophy, concerned with formal and final causes, in contrast with physics which studies the material and the efficient. Metaphysics is a more general and more abstract discipline than physics, and rests on it, just as physics in turn rests on a foundation of natural history. The image is that of a pyramid whose vertex is the summary law of nature, known to God but perhaps beyond the bounds of human enquiry.

Rather unusually, Bacon made a distinction between metaphysics and *philosophia prima* – primitive or summary philosophy. The three main subdivisions of philosophy are not like lines meeting at a point, but like branches of a tree that join in a common stem. Arboreal metaphors of this kind may appear to suggest the Cartesian picture of science, in which the trunk of physics grows out of and is sustained by the roots of an a priori metaphysical system, but the reality is quite different. Bacon's *philosophia prima* is a mere receptacle for such miscellaneous principles as have applications in several different disciplines – for example, that the force of an agent is increased by the reaction of a contrary, a rule with applications in both physics and politics.

Bacon's most important innovation was, however, the close linking of theoretical and practical disciplines. In the Aristotelian tradition these had been kept quite separate, but now (within natural philosophy at least) each speculative discipline was to have its operative counterpart: corresponding to physics there would be mechanics; corresponding to metaphysics, natural magic. Bacon had no illusions about the pervasive fraudulence of the magical tradition, but – as in the parallel case of astrology – he sought reform, not abolition (see Alchemy).

This close association of theory and practice was of the utmost importance: Bacon saw the dismal record of earlier natural philosophy as stemming very largely from their divorce. The practitioners of the applied arts had made what progress they had in a purely empirical way, unaided by any method, while the philosophers – especially, although not exclusively, the schoolmen in the universities – had disdained experience and, like spiders, had spun metaphysical cobwebs out of their own insides. The only hope of progress lay in uniting the two approaches.

4 The new logic

The *Novum Organum* has had far fewer readers than either the *Essays* or *The Advancement of Learning*, partly because of its more difficult subject matter, and partly because it was written in Latin; it is, however, Bacon's most remarkable achievement, and the one which he himself regarded most highly. It cost him considerable trouble – William Rawley, his chaplain, described having seen no fewer than a dozen drafts revised year by year in the decade preceding publication. Bacon's chosen form is the aphorism: initially these are short and highly compressed, but as the work proceeds they grow longer. In the second book, clearly less thoroughly revised, Bacon's grip slackens and then loosens altogether, and the aphoristic form is abandoned except in appearance.

As its title makes plain, the *Novum Organum* was intended as an account of a new logic, designed to replace the Aristotelian syllogistic which Bacon saw as having hampered and indeed corrupted the investigation of nature. The full exposition of this is found in Book II; Book I contains a survey of the task and its difficulties.

The basic themes of the *Novum Organum* are set out in the first three aphorisms:

> Man, being the servant and interpreter of nature, can only do and understand so much . . . as he has observed in fact or in thought of the order of nature: beyond this he neither knows anything nor can do anything. Neither the naked hand nor the understanding left to itself can effect much. It is by instruments and helps that the work is done, which are as much wanted for the understanding as for the hand. And as the instruments of the hand either give motion or guide it, so the instruments of the mind supply either suggestions for the understanding or cautions.
>
> Human knowledge and human power meet in one, for where the cause is not known the effect cannot be produced. Nature to be commanded must be obeyed; and that which in contemplation is as the cause is in operation as the rule.
>
> (Bacon 1620: i.1–3)

Natural philosophy needs to begin with observation. Though Bacon sharply separated himself from those whom he classed as 'empirics', his objection to them lay in their lack of method and consequent recourse to unsystematic experimentation, not in their reliance on experience itself. Method is absolutely essential: unmethodical experimentation is mere groping in the dark, and is no more likely to

produce results than digging for buried treasure on a purely random basis.

It is an essential feature of the new method that it can be openly described, explained and taught. The new reformed science is seen as an essentially collective activity; though undoubtedly presupposing a certain minimum of intelligence in its operatives, such an enterprise does not require, and is therefore not dependent on, the appearance of individual genius:

> But the course I propose for the discovery of sciences is such as leaves but little to the acuteness and strength of wits, but places all wits and understandings nearly on a level. For as in the drawing of a straight line or perfect circle, much depends on the steadiness and practice of the hand, if it be done by aim of hand only, but with the aid of rule or compass, little or nothing; so it is exactly with my plan.
> (Bacon 1620: i.61)

There is therefore nothing intuitionistic about Bacon's approach, nothing at all resembling the Cartesian reliance on clear and distinct ideas. Bacon distrusted any appeal to the supposedly self-evident at the outset of any enquiry. Validation could only be retrospective: it was the ability of a theory to endow its holders with power over nature that provided the best, and indeed the only genuinely satisfactory, evidence for its truth.

Previous attempts at discovery had failed because men had either complacently supposed the mind already to be adequately equipped for the task, or else had despaired altogether. Nature is comprehensible, but its subtlety far exceeds that of the human mind. In order for anything to be achieved, a new logic based not on the *anticipation* but on the *interpretation* of nature needs to be brought into use.

This contrast between anticipation and interpretation is central to Bacon's conception of his project. Anticipations are not hypotheses, but rather 'the voluntary collections that the mind maketh of knowledge; which is every man's reason' ([*c*.1603] *Works* III: 244). The root idea is one of superficiality: these are the notions of 'folk physics' – popular ordinary-language concepts such as arise in the ordinary conduct of life, sometimes refined and made more abstract by the labours of philosophers, but not fundamentally altered. 'There is no stronger or truer reason why the philosophy we have is barren of effects than this, that it has caught at the subtlety of common [*vulgarium*] words and notions, and has not attempted to pursue or investigate the subtlety of nature' ([*c*.1607] *Works* V: 421).

It was the all-pervasive unsoundness of the concepts used that made the old logic useless as a tool for the investigation of nature. Syllogisms incorporating confused and badly abstracted terms merely propagate error without supplying any means of correcting it; more generally, the teaching of deductive logic encourages the natural tendency of the mind to ascend hurriedly and without due examination to propositions of great generality, and then to regard these as securely established when investigating further. Bacon's method requires not the liberation but the regulation of the intellect, which *'must not . . . be supplied with wings, but rather hung with weights, to keep it from leaping and flying'* (1620: i.104).

Just as syllogisms are useless for any enquiry into nature, so too is the induction by simple enumeration described in logic textbooks. Bacon consistently regarded this with contempt – 'childish' was his favourite term of abuse. It operated on the surface of things, employing 'popular' notions, and was for that reason incapable of delivering certainty. Bacon was no fallibilist, prepared to settle for a natural philosophy of conjectures and merely provisional conclusions. Certainty was quite as important for him as it would be for Descartes, but what he was looking for was certainty of a very different kind – not immunity from sceptical doubt, but complete reliability. This could be furnished by induction, but it would have to be induction of a new and much more elaborate kind, one that could make use of negative as well as positive instances.

5 The idols of the mind

Before the new logic could be put to use, the weaknesses of the human mind which it was designed to correct or evade needed to be analysed. The central section of Book I is a counterpart to the analyses of sophistical reasoning provided in the logic textbooks. What emerged, however, was not merely a list of inductive fallacies, but rather one of the most memorable and original parts of Bacon's system.

Bacon distinguished four classes of idols. The 'Idols of the Tribe' arise from the limitations of human nature; they can be allowed for and guarded against, but not removed entirely. Bacon had in mind such weaknesses as the tendency to suppose more regularity than actually exists, to be over-influenced by the imagination, and even more by hopes and desires. A very different kind of limitation arises from the dullness of the senses. Bacon had no sympathy with radical sceptical doubts of the kind that were to preoccupy Descartes, but he was acutely aware of the weakness of the human senses, and of their complete incapacity to discern the secret workings of nature. The problem was not one to be abandoned to sceptical despair or solved by metaphysical validation. Some assistance could be

gained from the use of instruments, but the real solution lay in experimental design. Hidden processes would be linked with observable consequences, and an experimental determination of the latter would reveal the nature of the former.

The 'Idols of the Cave' arise from the idiosyncrasies of individuals, either natural or implanted by education. Some minds are good at seeing distant resemblances, others at making fine distinctions; some are attracted to ancient wisdom, or what might pass for it, others only to novelty; almost everyone is influenced by those disciplines which they know well, and even more by those to which they have contributed.

The 'Idols of the Forum' (or 'Idols of the Market Place') arise from the deficiencies of human speech. Bacon had no respect for the categories of ordinary language, or the habitual thought-patterns of the uneducated; 'popular' is in his lexicon almost invariably a term of disparagement. Words devised for the ordinary purposes of life cannot provide a satisfactory vocabulary for natural philosophy, and attempts to remedy the situation by making definitions achieve nothing: words are defined by other words, which themselves share the same defects.

These three classes of idols can be guarded against and to some extent allowed for, but never extirpated entirely. The fourth class is in this respect different. This consists of the 'Idols of the Theatre' – the point of the name was that rival philosophies were like stage-plays, with different casts and different plots, but all equally fictitious. The potential variety of such systems is clearly unlimited, but Bacon distinguished three main types. The natural philosophy of Aristotle and his followers was corrupted partly by logic, and partly by a reliance on common notions – popular conceptions quite unsuited to the task in hand. The empirical school (exemplified by the alchemists, but also including William Gilbert who investigated magnetism) was misled by too narrow a line of experimental enquiry: restricted ranges of data fill the imagination and lead to one-sided accounts of the world in chemical or magnetic terms. Platonism (Bacon had in mind not so much the doctrines of Plato himself – whom he generally treats with respect – as the Platonism of his own era) (see Platonism, Renaissance) was worst affected of all, being corrupted by theology and superstition. Bacon's own religious views are by no means easy to discern and have been very diversely interpreted, but one thing that is abundantly clear is that he was wholly opposed to the intrusion of religious doctrines, Christian or non-Christian, into natural philosophy; the result of allowing this to happen was a corruption of both, into a superstitious philosophy and a heretical religion.

6 Induction

Bacon's methodological proposals occupy Book II of the *Novum Organum*. The first stage in any investigation is the gathering together of a natural and experimental history. This might be quite broad in scope – for example, the history of heat in aphorisms 11–18 – but it could be much more narrowly focused: Bacon's own examples include histories of the rainbow, of honey and of wax. The idea of a natural history was an old one, going back through numerous Renaissance and medieval encyclopedias to Pliny, and ultimately to Aristotle's *Historia Animalium*. Bacon, however, made an innovation of crucial importance. His histories would record not only material gathered from the ordinary workings of nature, but also novel phenomena generated by human activity. In the Aristotelian tradition such artefacts would have been discounted as inappropriate material for investigation; Bacon, however, saw them not merely as legitimate subjects of enquiry, but as especially valuable: 'by the help and ministry of man a new face of bodies, another universe or theatre of things, comes into view' (*Works* IV: 253). Nature was to be put to the question – a contemporary euphemism for torture.

Histories of this kind could not be assembled quickly, and the whole project would clearly absorb a very large amount of labour and money. Bacon was acutely aware of this, but could see no alternative. The human understanding needed to be purged and cleansed, and this had to be done not by any Platonic (or Cartesian) detachment from the data of the senses, but by an immersion into the world of experience in its full individuality and variety. Bacon was a good nominalist in the English tradition: for him, individuals alone are real and our most reliable cognitions are our direct sensory awareness of them. Withdrawal to a world of abstract objects supposedly accessible to reason leads merely to illusion and the enunciation of empty generalities; for Bacon the word 'abstract' – like 'popular' – almost invariably carries negative connotations.

We have to begin, therefore, with particulars; we have also to begin with as full a range of particulars as possible. Bacon did not require all this data to be correct, though manifestly false material ought to be kept out where possible, and dubious reports marked as such. Some falsehoods were bound to creep in, but these could be dealt with; what could not be dealt with were biases which affected the whole history. Initial attempts to impose criteria of relevance had therefore to be outlawed altogether.

Most histories would contain an immense quantity of data – far too much for any individual

human mind to grasp as a whole – and an ordering of this material into some kind of structure was essential. Bacon proposed the use of three tables: first a ‘Table of Essence and Presence’, listing all the situations in which the nature under investigation is present; then a ‘Table of Deviation or Absence in Proximity’, describing all those situations which are as close as possible to those in the first table but where the nature under investigation is absent; and finally a ‘Table of Degrees or Comparison’, a list of those situations where the nature in question varies in intensity, together with details of the circumstances accompanying that variation.

When first drawn up, the second and third tables would both, in general, be incomplete in that they would contain gaps corresponding to entries in the first. One of the chief functions of experiment was to remedy these defects: for example, given that the rays of the sun can be concentrated by a convex lens, a trial should be made to see whether such lenses can produce heat by focusing the rays of the moon, or any rays proceeding from heated stones or vessels containing boiling water.

When the tables have been drawn up it is possible to begin the inductive process itself:

> The first work therefore of true induction . . . is the rejection or exclusion of the several natures which are not found in some instance when the given nature is present, or are found in some instance where the given nature is absent, or are found to increase in some instance where the given nature decreases, or to decrease where the given nature increases.
> (1620: ii.16)

Only when this process of exclusion has been completed will it be possible to grasp the true essence (or form, to use Bacon’s own term) of the nature in question.

This method clearly rests on several presuppositions, of which the most fundamental is a principle of limited variety. Though the world as we experience it appears unendingly varied, all this complexity arises from the combination of a finite, and indeed quite small, number of simple natures. There is an alphabet of nature, which cannot be guessed or discovered by speculation, but which will start to be revealed once the correct investigatory procedures are employed. The time needed is indeed not merely finite but quite short: once the natural histories are complete, the unearthing of all the secrets of nature will require no more than a few years.

Bacon also assumed there to be a direct one-to-one correlation between natures and the forms from which they arise. He was aware that critics might deny this and maintain (for example) that the heat of the heavenly bodies and of fire, or the red in a rose and in a rainbow, are only apparently similar, having quite different causes in reality. Bacon firmly denied this – however apparently heterogeneous, these things agree in the forms or laws which govern heat and redness; indeed even such diverse modes of death as by drowning, by hanging and by stabbing agree in the form or law which governs death.

This way of thinking reinforces a tendency already present in the alchemical tradition of considering bodies as collections of simple natures, each explicable (and therefore reproducible) in isolation. Bacon certainly did think in this way: gold is yellow, heavy, ductile, fixed (that is, unaffected chemically by fire) and so on. Whoever knows the forms of these natures can attempt to join them together in a single body, and thereby transform that body into gold. At other times, however, Bacon seems to have recognized that forms are seldom independent: ‘since every body contains in itself many forms of natures united together in a concrete state, the result is that they severally crush, depress, break, and enthrall one another, and thus the individual forms are obscured’ (1620: ii.24). They are not, however, hidden altogether: since expansion is part of the form of heat, all heated bodies must expand; but while the expansion of air is easily noticed, that of iron is less manifest to the senses.

The justification of the principles of limited variety and of the direct correlation of forms and natures could always be postponed; another problem, however, had to be faced at the outset. Exclusion involves the rejection of simple natures, ‘and if we do not yet possess sound and true notions of simple natures, how can the process of Exclusion be made accurate?’ (1620: ii.19). The old logic had proved inadequate because of this deficiency; what grounds are there for supposing that the replacement would fare any better?

Bacon was acutely aware of this problem and of the difficulty it posed for his project. His solution was to propose a series of supports of induction: the account of these occupies the last part of Book II of the *Novum Organum* and is (characteristically) lengthy, elaborate and unfinished; indeed all he managed to describe was the first of his nine kinds of support, the ‘Prerogatives of Instances’, of which he distinguished no fewer than twenty-seven different varieties. Bacon’s account of these demonstrates, perhaps more clearly than any other passage in his writings, the distinctive strengths and weaknesses of his mind. The discussion is often shrewd and sometimes much more – the *instantia crucis* has passed into modern science, under the name of a crucial experiment – but Bacon’s addiction to elaborate systems of classification and

portentous schemes of nomenclature is frequently apparent, above all in the nineteen species of motion described in aphorism 48. The immensity of his intellectual distance from such contemporaries as GALILEO is nowhere more apparent than it is here.

7 Natural philosophy

Bacon's intellectual gifts were remarkable, but they were not those of a scientist. He was a lawyer, and it was here, as well as with human affairs in general, that his real area of expertise can be found. He was widely read in natural philosophy, but his approach remained that of an outsider, albeit a shrewd and exceedingly intelligent one. These limitations became particularly apparent when Bacon turned to astronomy, the most highly developed of all contemporary scientific disciplines. He rejected Copernicanism and, although he saw many of the weaknesses of the inherited astronomical tradition, unlike Kepler he had only vague and quite unhelpful ideas about how the field might be reformed.

Bacon's own physics was fundamentally non-mechanistic. Bodies contain two types of matter – tangible and spiritual – and the operation of the latter, although never explained clearly, is certainly not conceived in mechanistic terms. Bacon did, however, employ several ideas that were to be taken over by the mechanical philosophers who followed him, in particular that the observable qualities of bodies are to be explained by the constitution of their internal parts. Glass can be made white by being crushed into tiny fragments, and water white by being beaten into foam; heat is not a scholastic real quality but a kind of motion. Later Baconians such as BOYLE and Hooke were able to take over these ideas and express them in more unambiguously mechanistic terms.

8 Bacon's influence

Bacon's philosophical writings met with little appreciation in England during the 1620s and 1630s. Admirers of the older learning, from James I downwards, were for the most part uncomprehending, and the one major scientist then practising, William Harvey, was brutally dismissive. Bacon had more impact in France, where he was carefully read by Mersenne, GASSENDI and DESCARTES, but even they only responded to selected parts of the system, notably the 'Idols' and the appeal to experiment.

The political turmoil in Britain in the 1640s stimulated a new interest in Bacon's thought, both among the advocates of universal reform like Samuel Hartlib, and among such natural philosophers as Robert Boyle and Robert Hooke. Baconianism indeed became the official philosophy of the Royal Society, celebrated in Thomas Sprat's semi-official *History* (1667). The hopes thus stimulated, however, proved difficult to satisfy. NEWTON paid little attention to Bacon, and the *Principia* was an achievement utterly unlike anything projected in the *Novum Organum*. Locke's debt was rather greater, especially in *The Conduct of the Understanding*, but by the early eighteenth century interest in Baconianism had started to decline.

Following the example of Voltaire, the French encyclopedists treated Bacon with great respect as an empirical, essentially secular thinker, to be contrasted favourably with Descartes who was now seen as scientifically discredited and too deferential to the Church. In Britain Bacon was ignored by HUME, but admired by REID who helped create a widely influential methodological synthesis of Baconian and Newtonian ideas.

The Baconian revival reached its climax in the second quarter of the nineteenth century. Sir John Herschel's *Preliminary Discourse on the Study of Natural Philosophy* (1830) was a thorough attempt to recast Baconianism in a form compatible with contemporary science. John Stuart MILL and William WHEWELL, though disagreeing about almost everything, both acknowledged a deep debt to Bacon, and to the inductive method of science. The most accessible introduction to early Victorian attitudes towards Bacon is however provided by Macaulay's essay 'Lord Bacon' (1837). Though respectful towards Bacon's thought, Macaulay took a less favourable view of his character, and it was in response to his account that James Spedding undertook the labours that led to his *Life and Letters* (1857–74: vols VIII–XIV), and to the critical edition of Bacon's works produced jointly with R.L. Ellis and D.D. Heath.

In the latter part of the nineteenth century, Bacon's reputation as a methodologist began to decline. The trend continued after 1900, Bacon's reputation reaching its nadir mid-century when Karl POPPER proposed a method for science that eschewed induction altogether, and historians such as Alexandre Koyré offered accounts of the scientific revolution that made Bacon's contribution utterly marginal. Since then there has been a modest revival, but Bacon has still not recovered an assured place in the philosophical canon.

J.R. MILTON

BACON, ROGER (*c.*1214–92/4)

Associated with both the University of Paris and Oxford University, Roger Bacon was one of the first in the Latin West to lecture and comment on Aristotle's writings on subjects other than logic. After he came to know Robert Grosseteste's work in natural philosophy, he became the advocate of a curricular reform that emphasized scientific experiment and the study of languages. His views were often unpopular, and he constantly belittled all who disagreed with him.

Bacon's work in logic and semantic theory had some influence during his lifetime and immediately after his death. His work in science, however, had little impact. His renown in the history of science is due in part to his being viewed as a precursor of the Oxford Calculators, who in turn anticipated certain important developments in seventeenth-century science.

GEORGETTE SINKLER

BAKHTIN, MIKHAIL MIKHAILOVICH (1895–1975)

Bakhtin is generally regarded as the most influential twentieth-century Russian literary theorist. His writings on literature, language, ethics, authorship, carnival, time and the theory of culture have shaped thinking in criticism and the social sciences. His name is identified with the concept of dialogue, which he applied to language and numerous other aspects of culture and the psyche.

Bakhtin viewed literary genres as implicit worldviews, concrete renditions of a sense of experience. Strongly objecting to the idea that novelists simply weave narratives around received philosophical ideas, he argued that very often significant discoveries are made first by writers and are then 'transcribed', often with considerable loss, into abstract philosophy. For example, he regarded the novelists of the eighteenth century as explorers of a modern concept of historicity long before philosophers took up the topic. He argued that considerable wisdom could be achieved by probing the form, as well as the explicit content, of literary works. In literature as in life, however, much wisdom is never fully formalizable, although we may approximate some of it and gesture towards more. Such partial recuperation was, in Bakhtin's view, the principal task of literary criticism.

Bakhtin's favourite genre was the realist novel. In his view, novels contain the richest sense of language, psychology, temporality and ethics in Western thought. He revolutionized the study of novels by arguing that traditional poetics, which employed categories suitable to poetry and to drama, had been unable to appreciate just what is novelistic and especially valuable about novels. Seeking the essence of 'prosaic intelligence', he therefore formulated an alternative to poetics, which critics have called 'prosaics'. This term also designates an important part of his worldview in approaching many other topics, especially language. Bakhtin stressed the prosaic, ordinary, unsystematic, events of the world as primary. In culture, order can never be presumed, but is always a 'task', the result of work that is never completed and always upset by everyday contingent events. Better than any other form of thought, great prose, especially realistic novels, captures this prosaic sense of life.

Believing in contingency and human freedom, Bakhtin described individual people, and cultural entities generally, as 'unfinalizable'. Human beings always manifest 'surprisingness' and can never be reduced to a fully comprehensible system. Paraphrasing the implications of Dostoevskii's novels, Bakhtin located humanness in the capacity of people 'to render *untrue* any externalizing and finalizing definition of them. As long as a person is alive he lives by the fact that he is not yet finalized, that he has not uttered his ultimate word' (*Problemy poetiki Dostoevskogo* 1929; original emphasis). Ethically, the worst act is to treat people as if some 'secondhand' truth about them were exhaustible. Psychologically,

> A man never coincides with himself. One cannot apply to him the formula of identity A ≡ A ... the genuine life of the personality takes place at the point of non-coincidence between a man and himself ... beyond the limits of all that he is as a material being ... that can be spied upon, defined, predicted apart from its own will, 'at second hand.'
>
> (*Problemy poetiki Dostoevskogo* 1929)

Bakhtin therefore opposed all deterministic philosophies and all cultural theories that understate the messiness of things and the openness of time. He rigorously opposed Marxism and semiotics, although, strangely enough, in the West his work has been appropriated by both schools. Stating his own thought as a paraphrase of Dostoevskii, he wrote:

> nothing conclusive has yet taken place in the world, the ultimate word of the world and about the world has not yet been spoken, the world is open and free, everything is still in the future and will always be in the future.
> (*Problemy poetiki Dostoevskogo* 1929)

GARY SAUL MORSON

BAKUNIN, MIKHAIL ALEKSANDROVICH (1814–76)

Bakunin was the leading proponent in the second half of the nineteenth century of a variety of anarchism rooted in a Romantic cult of primitive spontaneity, and one of the principal ideologists of Russian populism. But along with his public defence of the principle of 'absolute liberty' he attempted to set up networks of secret societies which were to direct the revolution and subsequently assume dictatorial powers. The contradiction between these two aspects of his activities has puzzled historians, many of whom have sought the answer in his personality, in which the urge to dominate was as strong as the urge to rebel.

AILEEN KELLY

BARTHES, ROLAND (1915–80)

In the field of contemporary literary studies, the French essayist and cultural critic Roland Barthes cannot be easily classified. His early work on language and culture was strongly influenced by the intellectual currents of existentialism and Marxism that were dominant in French intellectual life in the mid-twentieth century. Gradually his work turned more to semiology (a general theory of signs), which had a close association with the structuralist tradition in literary criticism. In his later work, Barthes wrote more as a post-structuralist than as a structuralist in an attempt to define the nature and authority of a text. Throughout his writings Barthes rejected the 'naturalist' view of language, which takes the sign as a representation of reality. He maintained that language is a dynamic activity that dramatically affects literary and cultural practices.

JAMES RISSER

BAUMGARTEN, ALEXANDER GOTTLIEB (1714–62)

The German philosopher Baumgarten is known primarily for his introduction of the word 'aesthetics' to describe the affects of art and nature, which in the course of the seventeenth century replaced the older theory of beauty. Baumgarten derived the term from the Greek *aisthanomai*, which he equated with the Latin *sentio*. He understood it to designate the outer, external or bodily sense, as opposed to the inner sense of consciousness. Thus aesthetics is the realm of the sensate, of sense perception and sensible objects. Baumgarten understood his usage to be consistent with classical sources, but he was aware also that he was extending logic and science into a new realm. Baumgarten's importance lay in adapting the rationalism of Leibniz for both the study of art and what came to be known after Kant as the aesthetic.

BAYLE, PIERRE (1647–1706)

Bayle was one of the most profound sceptical thinkers of all time. He was also a champion of religious toleration and an important moral philosopher. The fundamental aim of his scepticism was to curb the pretensions of reason in order to make room for faith. Human reason, he believed, suffers from two fundamental weaknesses: it has a limited capacity to motivate our actions, and it is more a negative than a positive faculty, better at uncovering the defects of various philosophical positions than at justifying any one of them. This conception of reason led Bayle to see, with an uncommon clarity, that the nature of the sceptic's arguments must be to proceed by internal demolition, showing how claims to knowledge undermine themselves in their own terms.

Bayle's moral thought is to be found essentially in his critique of attempts (such as that of Malebranche) to show how God, all-powerful and good, could have created a world in which there is evil. Such theodicies, he argued, rely on unacceptable models of moral rationality. Bayle's arguments reveal a view of moral reasoning that is of considerable interest in its own right. Like Malebranche (and contrary to Leibniz, who attacked Bayle's critique of theodicy), he believed that there are duties superior

to that of bringing about the most good overall. But unlike Malebranche, Bayle saw these duties as lying not in what the rational agent owes himself but in what he owes to the inviolable individuality of others. This outlook had its psychological roots, no doubt, in Bayle's own experience as a Huguenot victim of religious persecution.

CHARLES LARMORE

BEATTIE, JAMES (1735–1803)

James Beattie was famed as a moralist and poet in the late eighteenth century, and helped to popularize Scottish common-sense philosophy. At Marischal College, Aberdeen, Beattie cultivated a lecturing style which differed significantly from that of his Aberdonian predecessors. Because he believed that the form of abstract analysis characteristic of the science of the mind in his day often led students into the morass of Humean scepticism, Beattie endeavoured to inculcate sound moral and religious principles through the study of ancient and modern literature. Consequently his version of common-sense philosophy diverged from that developed by Thomas Reid. Beattie was more of a practical moralist than an anatomist of the mind, and his treatment of common-sense epistemology lacked the philosophical range and rigour of Reid's.

PAUL WOOD

BEAUTY

On the subject of beauty, theorists generally agree only on rudimentary points about the term: that it commends on aesthetic grounds, has absolute and comparative forms, and so forth. Beyond this, dispute prevails. Realists hold that judgments of beauty ascribe to their subjects either a nonrelational property inherent in things or a capacity of things to affect respondents in a way that preserves objectivity. In both cases acute problems arise in defining the property and in explaining how it can be known. Classical Platonism holds that beauty exists as an ideal supersensible Form, while eighteenth-century theorists view it as a quasi-sensory property. Kant's transcendental philosophy anchors the experience of beauty to the basic requirements of cognition, conferring on it 'subjective universality and necessity'. Sceptics complain that the alleged property is merely a reflection of aesthetic pleasure and hence lacks objective standing. Partly due to its preoccupation with weightier matters, the philosophic tradition has never developed any theory of beauty as fully and deeply as it has, say, theories in the domain of morality. Comparative neglect of the subject has been encouraged by the generally subjectivistic and relativistic bent of the social sciences and humanities, as well as by avant-gardism in the arts. However, several recent and ambitious studies have given new impetus to theorizing about beauty.

JOHN H. BROWN

BEAUVOIR, SIMONE DE (1908–86)

Simone de Beauvoir, a French novelist and philosopher belonging to the existentialist-phenomenological tradition, elaborated an anthropology and ethics inspired by Kierkegaard, Husserl, Heidegger and Sartre in *Pyrrhus et Cinéas* (1944) and *Pour une morale de l'ambiguïté* (The Ethics of Ambiguity) (1947). In her comprehensive study of the situation of women, *Le deuxième sexe* (The Second Sex) (1949), this anthropology and ethics was developed and combined with a philosophy of history inspired by Hegel and Marx. The most prominent feature of Beauvoir's philosophy is its ethical orientation, together with an analysis of the subordination of women. Her concept of woman as the Other is central to twentieth-century feminist theory.

EVA LUNDGREN-GOTHLIN

BECCARIA, CESARE BONESANA (1738–94)

Best known for writing *Dei Delitti e delle Pene* (On Crimes and Punishments), Beccaria was a leading figure of the Milanese Enlightenment who also wrote about political economy and rose to high office in the Lombard administration. His chief work combines contractarian and utilitarian arguments to offer a compromise theory of punishment. According to him, law operates as a sanction to deter harmful behaviour, and should be clear and equal for all. Punishments must be proportionate to the crime whilst preserving the liberty of individuals to pursue their interests to the benefit of themselves and society. He condemned torture and the death penalty for failing to meet these criteria.

RICHARD BELLAMY

BEHAVIOURISM, ANALYTIC

Analytical behaviourism is the doctrine that talk about mental phenomena is really talk about behaviour, or tendencies to behave. For an analytical behaviourist, to say that Janet desires ice

cream is to say that, all things being equal, she tends to seek it out. To say that Brad is now feeling jealous is to say no more than that he is now behaving in a way characteristic of jealousy, or perhaps that he would do so under appropriate provocation. Analytical behaviourism differs from methodological behaviourism in insisting that our ordinary use of mental language really is, in some sense, already about behaviour. The methodological version claims either that in doing psychology we should restrict ourselves to notions which can be defined behaviourally, or, sometimes, that our general psychological language, even if not already definable in this way, should be reformed in this general direction.

The most telling objection to this account of the mind is that it is inconsistent with the requirement that mental states are causes of behaviour. Ordinarily we might note that Brad has a tendency to display jealous behaviour with little provocation, and conjecture that this is caused by his feeling jealous (rather than, say, practising for his forthcoming part in a Jacobean tragedy). But according to analytical behaviourism his feeling jealous is merely his tendency to the behaviour, and since nothing causes itself, his jealousy cannot be the cause of the pattern of behaviour.

DAVID BRADDON-MITCHELL

BEHAVIOURISM, METHODOLOGICAL AND SCIENTIFIC

Methodological behaviourism is the doctrine that the data on which a psychological science must rest are behavioural data – or, at the very least, publicly observable data – not the private data provided to introspection by the contents of an observer's consciousness. *Scientific*, or, as it was sometimes called, 'radical', behaviourism contends that scientific psychology ought to be concerned only with the formulation of laws relating observables such as stimuli and responses; not with unobservable mental processes and mechanisms such as attention, intention, memory and motivation. Methodological behaviourism is all but universally embraced by contemporary experimental psychologists, whereas scientific behaviourism is widely viewed as a doctrine in decline. Both forms of behaviourism were articulated by J.B. Watson in 1913. B.F. Skinner was the most prominent radical behaviourist.

In addition to its empiricist strictures against inferred mental mechanisms, radical behaviourism was also empiricist in its assumptions about learning, assuming that: (1) organisms have no innate principles that guide their learning; (2) learning is the result of a general-purpose process, not of a collection of mechanisms tailored to the demands of different kinds of problems; and (3) learning is a change in the relation between responses and the stimuli that control or elicit them. Many of these ideas continue to be influential, for example, in connectionism.

C.R. GALLISTEL

BEING

Although 'being' has frequently been treated as a name for a property or special sort of entity, it is generally recognized that it is neither. Therefore, questions concerning being should not be understood as asking about the nature of some object or the character of some property. Rather, such questions raise a variety of problems concerning which sorts of entities there are, what one is saying when one says that some entity is, and the necessary conditions on thinking of an entity as something which is.

At least four distinct questions concerning being have emerged in the history of philosophy: (1) Which things are there? (2) What is it to be? (3) Is it ever appropriate to treat 'is' as a predicate, and, if not, how should it be understood? (alternatively, is existence a property?) and (4) How is it possible to intend that something is? Twentieth-century discussions of being in the analytic tradition have focused on the first and third questions. Work in the German tradition, especially that of Martin Heidegger, has emphasized the fourth.

MARK OKRENT

BELIEF

Introduction

We believe that there is coffee over there; we believe the special theory of relativity; we believe the Vice-Chancellor; and some of us believe in God. But plausibly what is fundamental is believing *that* something is the case – believing a proposition, as it is usually put. To believe a theory is to believe the propositions that make up the theory, to believe a person is to believe some proposition advanced by them; and to believe in God is to believe the proposition that God exists. Thus belief is said to be a propositional attitude or intentional state: to believe is to take the attitude of belief to some proposition. It is about what its propositional object is about (God, coffee, or whatever). We can think of the propositional object of a belief as the way the belief represents things as being – its content, as it is often called.

We state what we believe with indicative sentences in 'that'-clauses, as in 'Mary believes *that the Democrats will win the next election*'. But belief in the absence of language is possible. A dog may believe that there is food in the bowl in front of it. Accordingly philosophers have sought accounts of belief that allow a central role to sentences – it cannot be an accident that finding the right sentence is *the* way to capture what someone believes – while allowing that creatures without a language can have beliefs. One way of doing this is to construe beliefs as relations to inner sentences somehow inscribed in the brain. On this view although dogs do not have a public language, to the extent that they have beliefs they have something sentence-like in their heads.

An alternative tradition focuses on the way belief when combined with desire leads to behaviour, and analyses belief in terms of behavioural dispositions or more recently as the internal state that is, in combination with other mental states, responsible for the appropriate behavioural dispositions.

An earlier tradition associated with the British Empiricists views belief as a kind of pale imitation of perceptual experience. But recent work on belief largely takes for granted a sharp distinction between belief and the various mental images that may or may not accompany it.

1 *Beliefs as sentences in mentalese: the language of thought*

Fred's belief in the Devil cannot literally be a relation between Fred and the Devil. Otherwise he could not have the belief, unless the Devil existed. One response is to treat belief as a relation to sentences. To believe is to 'believe-true' a sentence: Fred believes-true 'The Devil exists'. But animals that lack a language have beliefs. My dog may believe that his master is home, or that it is time for a walk. Moreover, monolingual French speakers and monolingual English speakers may agree in what they believe, say, that it would be good if they knew more than one language, and yet they may not agree on which sentences they believe true. Finally, you might believe-true the sentence 'The Devil exists' and yet not believe that the Devil exists because you wrongly think that the word 'Devil' means 'God'. In this case what you believe is that God exists while wrongly thinking that the sentence 'The Devil exists' is a good sentence to use to express this belief. For these reasons, and others, belief is usually thought of as a relation to a proposition. A proposition is what is expressed by a sentence; it is what is in common between sentences in French and English that mean the same; the proposition expressed is what is grasped when you understand a sentence. Monolingual speakers believe alike by believing the same propositions; dogs have beliefs by virtue of believing propositions despite not having a language to express them; someone who believes that the sentence 'The Devil exists' is true while thinking that 'Devil' means 'God' does not thereby believe that the Devil exists because they are wrong about what proposition 'The Devil exists' expresses. These remarks slide over a lively controversy concerning the ontological status of propositions. Our immediate concern will be with a popular view that gives sentences a prominent role in the account of belief, but in a way which avoids the problems just rehearsed.

According to the language of thought hypothesis (LOTH), not only do certain sentences serve to provide the propositional objects of beliefs (and thoughts in general) but, in addition, the beliefs are themselves sentence-like. A sentence may be viewed as made up of significant parts put together according to certain rules. In the same general way, according to LOTH, beliefs have parts put together in certain ways (see Language of thought).

How does LOTH mesh with the idea that beliefs are relations to propositions? The idea is that a belief's propositional object is determined by how it is made up from parts which have representational or semantic properties – that is, the parts stand for things, properties and relations much as the parts of a natural-language sentence do (see Semantics). In English 'biscuit' represents certain things, and 'crisp' represents a certain property, and when we combine them together to form the sentence 'Biscuits are crisp' we get a sentence that makes a claim that is true or false according to whether or not the things have the property. This is how the sentence expresses the proposition that biscuits are crisp (see Compositionality). In the same way, there are brain structures that represent things and properties, and when these brain structures are put together in the right way we get, says LOTH, a more complex structure, a sentence in mentalese, that represents the things as having the properties – as it might be, the sentence of mentalese that says that biscuits are crisp, that expresses that proposition, and that thereby provides us with a token of the belief that biscuits are crisp.

This theory can allow that dogs have beliefs. Dogs might have a language of thought even though they do not have a public language. It can explain how monolingual speakers of different

language can agree in belief – their sentences of mentalese may express the same propositions. It also provides an explanation of a number of phenomena associated with belief. First, it explains how what a person believes can be causally relevant to what else they believe and what they do. If you believe that Mary is at the party and then learn that Mary is always accompanied at parties by Tom, you will typically come to believe that Tom is at the party. What you believe combines with what you learn to produce a new belief. LOTH explains these causal transactions as transactions between the structures that are the various beliefs. Much as a computer processes information by manipulating electronically coded structures, so we arrive at new beliefs by virtue of our brains manipulating the symbols of mentalese. Similarly, what we believe contributes to explanations of what we do. My belief that there is coffee over there together with suitable desires may lead me to move over there by virtue of its being a belief that there is coffee over there. LOTH accounts for this fact in terms of the causal influence of the sentences of mentalese on the causal path to bodily movement.

Second, LOTH explains the fact that typically one who can believe that Jill loves Mary can believe that Mary loves Jill, and in general if you can believe that *aRb*, then you can believe that *bRa* (the phenomenon known as systematicity). The fact that if you can believe that *aRb*, then you can believe that *bRa*, is explained by the fact that the state that encodes the former is a re-arrangement of the parts of the state that encodes the latter. And, of course, this explanation generalizes to explain more complex cases.

Finally, LOTH can explain our ability to form quite new beliefs (the property known as productivity). Just as we can form new sentences by novel combinations of the relevant words of a public language, so the brain can form new beliefs by means of novel combinations of the relevant words of mentalese.

LOTH thus explains a lot of what needs to be explained. Nevertheless, there are two serious problems for this view as applied to belief.

2 Two problems for LOTH

First, unless the claim that mentalese exists is trivialized – no matter what neuroscience reveals about how the brain processes information, what it reveals will count as the brain containing mentalese – LOTH involves risky speculation about how our brains work. The theory gives a hostage to fortune. Some are happy to accept this. If neuroscience reveals that there is no mentalese and that we do not process information in a sentential manner, we should say that we do not have beliefs and so embrace eliminativism about belief (see ELIMINATIVISM). This is, however, very much a minority view.

Second, LOTH leaves the intimate connection between belief and behaviour obscure. On the face of it predictions about the behaviour of highly complex organisms like ourselves should be enormously difficult. Trees bend in the wind whereas we put on jumpers, go inside houses, lean into the wind, cancel our games of tennis, or whatever. Unlike trees and simple machines, we respond to stimuli in enormously varied ways. Nevertheless we are quite good at predicting human behaviour. We all make many successful predictions of the following kind: someone who has uttered the word 'Yes' on hearing the sentence 'Would you like to come to dinner at 19.30 on the 21st?' will arrive around 19.30 on the 21st at the house of the person the sentence came from. What we do, of course, is use hypotheses about what people believe and desire and predict in terms of the rule that subjects will tend to behave in such a way that they achieve what they desire if what they believe is true. Our subject's 'Yes' tells us what they desire, and what we predict – their turning up at the named time – is behaviour that will achieve their desire for dinner.

Now we noted above how LOTH explains the way belief contributes to causing behaviour. In the same general way it explains how belief together with desire explains behaviour. For LOTH treats desires as like beliefs in being internal sentences of mentalese. The difference is that, as it is often put, the desires are stored in the 'desire' box, and the beliefs are stored in the 'belief' box. The metaphor of different locations marks the fact that beliefs and desires differ in how they relate to the world. Belief is a state that seeks to conform to how things are – the sight of coffee tends to extinguish my belief that there is no coffee near; whereas desire is a state that seeks to conform things to how it is – desire for coffee tends to bring one near coffee. The stored sentences that do the first job count as being in the belief box; the stored sentences of mentalese that do the second job count as being in the desire box. So the way belief and desire combine to produce behaviour is not a problem for the LOTH. The two 'differently located' stored sentences get together to produce the behaviour.

The problem, rather, arises from the fact that the connection between behaviour and what subjects believe and desire is most immediately one between behaviour and a rich system of belief and desire. Individual beliefs and desires grossly underdetermine behaviour. There is no behaviour that the belief that there is a mine near the tree, together with the desire to live, points to as such. It is, rather,

a rich system of belief – to the effect, say, that there is a mine near the tree, that the mine is likely to be triggered by going near it, that moving one's legs in such and such a way will not bring one near the tree, that there is not a bigger mine that can only be avoided by going close to the tree, that triggering mines tends to cause death, and so on and so forth, along with the desire to live being greater than the desire to test out the trigger system of the mines – that points to behaviour. When we give little illustrations of connections between subjects' beliefs and desires and what they do, we take for granted a great deal about what they believe and desire. This is fine. It is by and large common knowledge. But the point remains that only rich systems of belief and desire have the intimate connection with behaviour. The same point could be made with the dinner invitation story. The prediction of our subject's behaviour assumed a great deal by way of belief and desire. We assumed beliefs about what the words mean, about who uttered them, about which month was intended, . . . , and we assumed that there were no countervailing desires that outweighed the desire to go to dinner.

The problem for LOTH is that it takes as its starting point individual beliefs and desires. This leaves it seriously unclear what the theory has to say about the connection between a rich story about belief and desire, on the one hand, and behaviour, on the other. There is no behaviour that the individual belief that *p* and desire that *q* point to. *It is rich systems of both belief and desire that point in some reasonably determinate way to behaviour.* The challenge for LOTH is to find some kind of guarantee that the account of individual beliefs and desires it offers is such that if subjects have rich enough sets of these individual beliefs and desires, these rich enough sets of beliefs and desires will cause the reasonably determinate behaviour that tends to satisfy their desires if their beliefs are true.

3 Belief as a map by which we steer

One obvious fact about belief is the way we use sentences to state what we believe. An equally obvious fact is the connection between belief and behaviour via desire discussed above. F.P. Ramsey (1931) famously captured this idea by describing belief as a map by which we steer. The alternative to LOTH is an account of belief that sees belief as map-like.

For LOTH, individual beliefs are fundamental; while on the map view systems of belief are fundamental. Inside us is a hugely complex structure that richly represents how things around us are in an essentially holistic way. When you believe the bank is bigger than the post office, there is no individual structure, no sentence of mentalese in your head, that represents your belief that the bank is bigger than the post office. Rather you believe that the bank is bigger than the post office by having a belief system according to which, among a great many other things, the bank is bigger than the post office. The key point can be made in terms of maps. A map of the Earth might represent the fact that the taller mountains are mostly near the deeper oceans, but there is no part of the map that says just that in the way that there may be a sentence that says just that – for instance the very sentence 'The taller mountains are mostly near the deeper oceans'. Or consider holograms. Holograms are 'laser photographs'. When light from the laser is projected through the negative, the well-known, three dimensional, coloured array is produced. The negative can be thought of as representing things as being the way the coloured array depicts them. However, no part of the negative has special responsibility for some part of the array. Each part contains information about the whole array. In consequence, what happens if you damage part of the hologram is a loss of detail, a blurring, of the three dimensional array, not a loss in any particular part of it.

Many of the phenomena explained by LOTH can equally be explained by the map theory. We noted how LOTH can explain the evolution of belief over time in terms of the causal interactions of the internal sentences with each other, and how beliefs cause behaviour in terms of how the stored sentences figure in the causal path to behaviour. But internal maps guide rockets to their targets and evolve over time. The same goes for the maps we use every day – they guide our behaviour and evolve over time. We noted that LOTH can explain the fact that those with the capacity to believe that the bookshop is bigger than the post office are also able to believe that the post office is bigger than the bookshop. But maps (and holograms) that can represent that the bookshop is bigger than the post office can equally represent that the post office is bigger than the bookshop.

It has recently been argued that there is empirical evidence that our brains represent how things are around us in something like the way an internal map or hologram might. This has led to a renewed interest in the map theory of belief (see CONNECTIONISM).

The major question for the map theory concerns whether believing is closed under entailment. On the map theory to believe that *p* is to have a system of belief according to which *p*; that is, to have a system that could not be true unless *p*. But if *p* entails *q*, then a system that could not be true unless *p* must also be a system that could not be true unless *q*.

This means that the map view must accept closure under entailment, the principle that if *p* entails *q*, anyone who believes *p* believes *q*. But is it not possible to believe that a triangle is equiangular without believing that it is equilateral – as many beginning geometry students know only too well? The usual reply by map theorists is to insist that one who believes that a triangle is equiangular does believe that it is equilateral; what they may lack is knowledge about the right words to capture what they believe. But this is a matter of lively debate.

BELINSKII, VISSARION GRIGORIEVICH (1811–48)

Belinskii was considered by his followers in the nineteenth century, and by the official ideology of the Soviet period, to be not only Russia's greatest literary critic, but also a leading Russian thinker. Soviet encyclopedias label him 'critic, publicist and philosopher'. His role in Russian cultural life has been given positive as well as negative assessments, but there can be no doubt as to his huge influence. He is largely responsible for the fact that Russian literature and art, for a century and a half now, have been considered an organ of society, a mirror of the Russian nation's destiny and a vehicle of its historical progress. It is largely his merit – or fault – that in Russia, art and literature have been accorded a lofty status of leadership and authority, and also that 'art for art's sake' never became respectable there. The influence of Belinskii's philosophy of art extended through the entire political spectrum, far beyond his political legacy which was limited to the revolutionary left. The idea that art and literature are organic functions of society, nationhood and historical progress, which Belinskii took for granted, was passed on even to the Slavophile right and the liberal Westernizing centre. It remains an integral part of the doctrine of Socialist Realism.

VICTOR TERRAS

BELL'S THEOREM

Bell's theorem is concerned with the outcomes of a special type of 'correlation experiment' in quantum mechanics. It shows that under certain conditions these outcomes would be restricted by a system of inequalities (the 'Bell inequalities') that contradict the predictions of quantum mechanics. Various experimental tests confirm the quantum predictions to a high degree and hence violate the Bell inequalities. Although these tests contain loopholes due to experimental inefficiencies, they do suggest that the assumptions behind the Bell inequalities are incompatible not only with quantum theory but also with nature.

A central assumption used to derive the Bell inequalities is a species of no-action-at-a-distance, called 'locality': roughly, that the outcomes in one wing of the experiment cannot immediately be affected by measurements performed in another wing (spatially distant from the first). For this reason the Bell theorem is sometimes cited as showing that locality is incompatible with the quantum theory, and the experimental tests as demonstrating that nature is nonlocal. These claims have been contested.

ARTHUR FINE

BENJAMIN, WALTER (1892–1940)

Walter Benjamin was one of the most influential twentieth-century philosophers of culture. His work combines formal analysis of art works with social theory to generate an approach which is historical, but is far more subtle than either materialism or conventional *Geistesgeschichte* (cultural and stylistic chronology). The ambiguous alignment of his work between Marxism and theology has made him a challenging and often controversial figure.

JULIAN ROBERTS

BENTHAM, JEREMY (1748–1832)

Jeremy Bentham held that all human and political action could be analysed in terms of pleasure and pain, and so made comprehensible. One such analysis is how people actually do behave; according to Bentham, by seeking pleasure and avoiding pain.

Another such analysis is of how they ought to behave. For Bentham, this is that they should maximize utility, which for him is the same as producing the greatest happiness of the greatest number, which, again, is the same for him as maximizing pleasure and minimizing pain. His chief study was planning how there could be a good system of government and law; that is, how laws could be created so that people being as they actually are (seeking their own pleasure) might nevertheless do what they ought (seek the greatest pleasure of all). The instruments which government use in this task are punishment and reward, inducing action by threats and offers. For Bentham, punishment is done not for the sake of the offender, but to deter other people from doing the same kind of thing. Hence on his theory it is the apparent punishment which does all the good, the real punishment which does all the harm.

Bentham thought that the primary unit of significance was the sentence, not the word. He used this idea to produce profound analyses of the nature of law and legal terms, such as' right', 'duty' or 'property'. These are what he calls names of fictions – terms which do not directly correspond to real entities. However, this does not mean that they are meaningless. Instead, meaning can be given to them by translating sentences in which they occur into sentences in which they do not occur. Thus legal rights are understood in terms of legal duties, because sentences involving the former can be understood in terms of sentences involving the latter; these in turn can be analysed in terms of threats of punishment or, again, pleasure and pain. This gives sense to legal rights, but sense cannot be given in the same way to natural rights. For Bentham, we have no natural rights and the rights that we do have, such as property rights, are created by government, whose chief task is to protect them. Bentham also worked out how people could be protected from government itself, designing an elaborate system of constitutional law in which representative democracy was a central element.

Bentham invented the word 'international', and when he died he had an international legal and political influence. His chief influence in philosophy has been as the most important historical exponent of a pure form of utilitarianism.

ROSS HARRISON

BERDIAEV, NIKOLAI ALEKSANDROVICH (1874–1948)

Nikolai Berdiaev, Russian religious idealist, was one of many non-Marxist thinkers expelled from Russia by communist authorities in 1922. Although attracted to Marxism in his youth, even then he tempered it with a Neo-Kantian ethical theory. Well before the Bolshevik Revolution, he became seriously disenchanted with Marxist philosophy (though not with the idea of socialism) and embarked on the career of elaborating a personalistic Christian philosophy that occupied him for the rest of his life.

Dubbed 'the philosopher of freedom', Berdiaev wrote prolifically on that subject and on related topics in metaphysics, philosophy of history, ethics, social philosophy and other fields (but not epistemology, which he rejected as a fruitless exercise in scepticism). Because his approach to philosophy was admittedly anthropocentric and subjective, he accepted the label 'existentialist' and acknowledged his kinship with Dostoevskii, Nietzsche and (to a lesser degree) Jaspers. Like them, he constructed no philosophical system, though he did expound views that were coherently interrelated in the main, if impressionistically and sometimes obscurely expressed. Among his more prominent ideas were his conception of freedom (for which he was indebted to the mystical philosophy of Jakob Boehme), his distinction between spirit and nature, his theory of 'objectification', his doctrine of creativity and his conception of time.

The most frequently translated of twentieth-century Russian thinkers, Berdiaev has been widely studied in the West since the 1930s, particularly in schools of religion and theology and by philosophers in the existentialist and personalist traditions. Although many Western readers considered him the voice of Russian Orthodox Christianity, his independent views drew fire from some Orthodox philosophers and theologians and also from strongly anti-Soviet Russian émigrés. His writings while an émigré were eagerly embraced in his homeland once they could be published there, beginning in the late 1980s.

JAMES P. SCANLAN

BERGSON, HENRI-LOUIS (1859–1941)

So far as he can be classified, Bergson would be called a 'process philosopher', emphasizing the primacy of process and change rather than of the conventional solid objects which undergo those changes. His central claim is that time, properly speaking and as we experience it (which he calls 'duration'), cannot be analysed as a set of moments, but is essentially unitary. The same applies to movement, which must be distinguished from the trajectory it covers. This distinction, he claims, solves Zeno of Elea's paradoxes of motion, and

analogues of it apply elsewhere, for instance, in biology and ethics.

Bergson makes an important distinction between sensation and perception. He repudiates idealism, but claims that matter differs only in degree from our perceptions, which are always perfused by our memories. Perception free from all memory, or 'pure' perception, is an ideal limit and not really perception at all, but matter. Real perception is pragmatic: we perceive what is necessary for us to act, assisted by the brain which functions as a filter to ensure that we remember only what we need to remember. Humans differ from animals by developing intelligence rather than instinct, but our highest faculty is 'intuition', which fuses both. Bergson is not anti-intellectualist, though, for intuition (in one of its two senses) presupposes intelligence. He achieved popularity partly by developing a theory of evolution, using his *élan vital*, which seemed to allow a role for religion. In ethics he contrasted a 'closed' with a (more desirable) 'open' morality, and similarly contrasted 'static' with 'dynamic' religion, which culminates in mysticism.

BERKELEY, GEORGE (1685–1753)

Introduction

George Berkeley, who was born in Ireland and who eventually became Bishop of Cloyne, is best known for three works that he published while still very young: *An Essay towards a New Theory of Vision* (1709), *Three Dialogues between Hylas and Philonous* (1713), and in particular for *A Treatise concerning the Principles of Human Knowledge* (1710). In the *Principles* he argues for the striking claim that there is no external, material world; that houses, trees and the like are simply collections of 'ideas'; and that it is God who produces 'ideas' or 'sensations' in our minds. *The New Theory of Vision* had gone some way towards preparing the ground for this claim (although that work has interest and value in its own right), and *the Dialogues* represent Berkeley's second attempt to defend it. Other works were to follow, including *De Motu* (1721), *Alciphron* (1732) and *Siris* (1744), but it was the three early works that established Berkeley as one of the major figures in the history of modern philosophy.

The basic thesis was certainly striking, and from the start many were tempted to dismiss it outright as so outrageous that even Berkeley himself could not have taken it seriously. In fact, however, Berkeley was very serious, and certainly a very able philosopher. Writing at a time when rapid developments in science appeared to be offering the key to understanding the true nature of the material world and its operations, but when scepticism about the very existence of the material world was also on the philosophical agenda, Berkeley believed that 'immaterialism' offered the only hope of defeating scepticism and of understanding the status of scientific explanations. Nor would he accept that his denial of 'matter' was outrageous. Indeed, he held that, if properly understood, he would be seen as defending the views of 'the vulgar' or 'the Mob' against other philosophers, including Locke, whose views posed a threat to much that we would ordinarily take to be common sense. His metaphysics cannot be understood unless we see clearly how he could put this interpretation on it; and neither will we do it justice if we simply dismiss the role he gives to God as emerging from the piety of a future bishop. Religion was under threat; Berkeley can probably be judged prescient in seeing how attractive atheism could become, given the scientific revolution of which we are the heirs; and though it could hardly be claimed that his attempts to ward off the challenge were successful, they merit respectful attention. Whether, however, we see him as the proponent of a fascinating metaphysics about which we must make up our own minds, or as representing merely one stage in the philosophical debate that takes us from Descartes to Locke and then to Hume, Kant and beyond, we must recognize Berkeley as a powerful intellect who had an important contribution to make.

1 Life

George Berkeley was born in (or near) the town of Kilkenny, Ireland, and educated at Kilkenny College and at Trinity College, Dublin, where he took the degree of B.A. in 1704, and that of M.A. in 1707, becoming a Junior Fellow in the latter year. Before long he published the books for which he is now most renowned. However, mention must first be made of two notebooks, now known as the

Philosophical Commentaries, which he filled during the years 1707–8. Since their first publication in 1871 (but more particularly since it was established that they had at some stage been bound together in the wrong order, thus giving a distorted picture of the development of Berkeley's thought) these have proved an invaluable resource for scholars seeking to understand the evolution of his thinking during this crucial period. The major fruits of that thinking were *An Essay towards a New Theory of Vision* (1709), *A Treatise concerning the Principles of Human Knowledge* (1710) – which was originally intended to be merely Part I of a three- or four-part work– and the *Three Dialogues between Hylas and Philonous* (1713), which Berkeley published after he had moved to London. In between the *Principles* and *Dialogues* he published a slighter work, *Passive Obedience* (1712), which gives the main insight into his thinking on ethics, and on the basis of which he has been described as a theological rule-utilitarian. Also dating from about this time are essays published in Richard Steele's *Guardian* during the year 1713, which evidence Berkley's disdain for the anti-religious sentiments of the 'free-thinkers'.

From this time onwards, Berkeley's life was active and interesting. He made two continental tours, the first (1713–14) as chaplain to Lord Peterborough, during which he apparently met Malebranche, and the second (1716–20) as tutor to George Ashe, son of the Bishop of Clogher. Towards the end of the second tour he wrote the Latin tract *De Motu* for submission to the Royal Academy of Sciences at Paris, which had offered a prize for an essay on the cause of motion. He published this in 1721, returned to Ireland in the same year, and was appointed Dean of Derry in 1724. Already, however, he had conceived a remarkable project that was to dominate his life for ten years. During the spring of 1722 he resolved to found a college on the island of Bermuda, and before long he set about soliciting support for and gaining a charter for St Paul's College, which would, had it come into existence, have educated a number of young Native Americans, as well as the sons of English planters.

In fact he never reached Bermuda but, newly married, he set sail for Rhode Island in 1728, where he stayed for over two years awaiting a promised government grant, and where his house is preserved as a monument to him. The grant never materialized, so there was to be no college, either in Bermuda or, as he had come to think would be preferable, on the mainland. His time in Rhode Island was not, however, wasted. While there he wrote *Alciphron: or the Minute Philosopher*, an attack on atheism and deism in dialogue form, which was published in 1732, the year after his return to London. He also became a friend of Samuel Johnson, later the first president of King's College, New York. Johnson's *Elementa Philosophica* (1752) is dedicated to Berkeley, and two letters from Johnson written in 1729 and 1730 (published with Berkeley's replies in volume 2 of the standard edition of Berkeley's *Works*) reveal that he was basically sympathetic to, but also an acute critic of, Berkeley's main metaphysical doctrines.

Certainly the same could not be said of Andrew Baxter, who in 1733 included as part of his *Enquiry into the Nature of the Human Soul* what was, in fact, the first extended critique of Berkeley's *Principles*. Baxter's tone was hostile throughout. Berkeley chose not to respond, though in the same year he did answer an anonymous critic of *The New Theory of Vision* – a third edition of which had been annexed to *Alciphron* – by publishing *The Theory of Vision, Vindicated and Explained*. He also published a revised edition of the *Principles* and *Dialogues* in 1734. *The Analyst* (1734), which criticizes Newton's doctrine of fluxions, also relates to his earlier work in that Berkeley refers back to his observations on mathematics in the *Principles*, and it may be that remarks Baxter had made on his treatment of the mathematicians there played at least a minor role in encouraging him to publish it. Berkeley does not name the critic who, he says, had challenged him to 'make good' what he had said in the *Principles*, but if it was Baxter he treats him dismissively as someone who 'doth not appear to think maturely enough to understand either those metaphysics which he would refute, or mathematics which he would patronize' (*The Analyst* §50).

However, Berkeley also had to think about securing his and his family's future, and his efforts to gain preferment in the church were rewarded in 1734 when he was appointed Bishop of Cloyne in Ireland. There, he thoroughly earned the reputation he has had ever since as 'the good Bishop'. The tangible legacy includes *The Querist* (1735–7), which evidences his concern for the economic wellbeing of Ireland, and *Siris* (1744), so successful at the time that it went through six editions in the year of publication but which is now regarded as little more than a curiosity. However, this was to be his last original publication of any substance. He remained in Cloyne almost to the end of his life, moving to Oxford, where one of his sons was to study, in the summer of 1752. He died there the following year.

2 Influences

The primary influence on Berkeley is unquestionably John Locke, whose *Essay concerning Human Understanding* Berkeley had studied as an undergraduate and continued to dwell on afterwards. The long introduction to Berkeley's *Principles* is for the most

part a sustained attack on the view that we can frame abstract ideas, focusing on Locke's account of abstraction. Illegitimate abstraction is ultimately blamed for the supposedly untenable distinction between primary and secondary qualities, the belief in 'material substance', and the view that objects have an existence distinct from 'ideas', all of which are features of Locke's position (see LOCKE, J. §§2–5). Yet Berkeley owed a great deal to Locke whom he likened in the notebooks to 'a Gyant' and who should be seen as his mentor as well as one of his philosophical targets. It is therefore understandable that Berkeley has most often been seen as the second of the three great British Empiricists, as successor to Locke and precursor of HUME, these three being placed in opposition to the three great Rationalist philosophers, DESCARTES, SPINOZA and LEIBNIZ. Certainly, it would be tempting to say that the importance of Locke's influence on Berkeley could hardly be overestimated, were it not for the fact that it sometimes has been.

If only as a corrective, then, it is important to stress that while it is evident that Locke was often in Berkeley's mind as he formulated his own position, and while there is no doubt that none of Berkeley's major works would have existed in their present form had Locke never published the *Essay*, Berkeley would have insisted that much more was at stake than whether Locke got things right. He targeted certain views and assumptions that were very widely held. Thus Locke is the only philosopher he actually identifies and quotes from in the attack on abstract ideas, but even there he sees himself as opposing, not simply some quirky view of Locke's, but one which, as he put it in a letter, 'Mr. Locke held in common with the Schoolmen, and I think all other philosophers' (*Works*, vol. 2: 293). These certainly included Malebranche, for example, who, Berkeley elsewhere complained, 'builds on the most abstract general ideas' (*Works*, vol. 2: 214). Again, when he says that 'Some there are who make a distinction betwixt *primary* and *secondary* qualities' (*Principles* §9), he really does mean 'some', and not just Locke; and the same could be said of his opposition to the notion of 'material substance'. In short, Berkeley often had his eye on other thinkers too, and some of these must also count as influences. As is now widely recognized, these included writers in the Cartesian tradition, most notably Malebranche but also probably Pierre Bayle.

The relationship between Berkeley and Descartes is interesting – after all, it was Descartes who had introduced a radical dualism of 'matter' and 'mind', and although Berkeley rejected matter, he adhered to a broadly Cartesian view of the mind (see DUALISM). However, MALEBRANCHE is particularly important in the story, both because Berkeley had studied his *De la recherche de la vérité* at an early stage, and because Berkeley's position struck many as remarkably close to that of Malebranche. In particular, Berkeley positively denies the existence of bodies 'without the mind', but Malebranche had already argued that it was impossible to prove their existence conclusively, thus paving the way for their dismissal. Again, Malebranche had insisted that there are no corporeal *causes,* and that, strictly speaking, God is the only cause, and Berkeley certainly holds that only spirits can act. Moreover, Malebranche held, and Berkeley at least suggested, that in perception, God's ideas are revealed to us. It is significant, then, that in his own day, despite his protestations, Berkeley was often seen as essentially a follower of Malebranche. We might note, finally, that while Malebranche had concluded that neither sense nor reason could conclusively establish the existence of bodies, he also held that faith in the Scriptures did require this belief. When in the *Principles* Berkeley considers a number of possible objections to his positive rejection of 'matter', this argument from the Scriptures is the last that he chooses to tackle. As he says, 'I do not think, that either what philosophers call *matter*, or the existence of objects without the mind, is any where mentioned in Scripture' (*Principles* §82).

There is evidence that BAYLE too was an early influence, and when, as in the preface to the *Principles*, Berkeley refers to 'those who are tainted with scepticism', arguments he found in Bayle's *Dictionnaire historique et critique* were probably towards the front of his mind. Bayle had offered arguments against regarding extension and motion as any more objective than colour or smell (which the Cartesians recognized as mere 'sensations'), and for the view that the notion of real extension (for Cartesians the essence of matter) involved contradictions. Strict reasoning, Bayle argued, would thus lead us to deny the existence of bodies, in the face of our (fortunately) ineradicable beliefs. Berkeley could welcome and adapt these arguments to the extent that he was concerned to reject bodies 'without the mind', and while, unlike Bayle, Berkeley firmly denied that they lead to scepticism or to any conflict with common sense, it is hardly surprising if many of his contemporaries took a different view. As Andrew Baxter saw it, Berkeley was committed to the conclusion that 'he has neither *country* nor *parents*, nor any *material body* (but that all these things are mere *illusions*, and have no existence but in the fancy' (*An Enquiry into the Nature of the Human Soul* 1733).

3 Berkeley's metaphysics

Berkeley is understandably best known for his (at first sight outrageous) claim that mind or spirit is the

only substance, and that it is God who produces 'sensations' or 'ideas' in our minds. From the beginning, many regarded this view as sceptical at best or insane at worst, and Berkeley recognized that this might be the initial reaction. It is, then, an important feature of his position that, if rightly understood, his standpoint will be seen as common sense, and in accord with the views of the unsophisticated 'vulgar'. The purpose of the present section is to sketch in very general terms how Berkeley could see things in this way.

To begin with, we can hardly make sense of Berkeley's position unless we see him as starting from an assumption that he took both to be obviously true and to be shared by other philosophers, which was that each of us is aware only of the 'ideas', 'sensations' or 'perceptions' that are somehow or other produced in our minds. On the most common view – that taken by Descartes and Locke for example – these are produced in us by external objects, which objects we do not perceive 'immediately' because, as Locke put it (whatever precisely he meant by it), 'the Mind ... perceives nothing but its own *Ideas*' (Locke, *Essay* IV 4: §3). Berkeley's first insight, and it is one that his reading of Malebranche and Bayle must have encouraged, was that if we set things up in this way – distinguishing between the 'ideas' we perceive and the 'real' objects which lie hidden beyond them – scepticism becomes inevitable. At best we can hypothesize the existence of 'real' objects as the *most likely* causes of our ideas, but then we are vulnerable to the suggestion that there could be other causes, including, most plausibly, God. There are other difficulties too. Berkeley found it widely admitted that it is quite unclear how inert 'matter' could act on minds so as to produce ideas or perceptions in them (and Malebranche and other 'occasionalists' had denied that it in fact does) (see OCCASIONALISM); moreover, Berkeley found only obscurities and incoherencies in the prevalent conceptions of 'material substance'. Yet the most fundamental insight was to follow.

This insight was that when we – ordinary men and women – talk of houses, mountains, rivers and so on, we are talking about what we experience or are aware of, not of occult objects that we are not directly aware of at all. It follows, or at least it seemed to Berkeley to follow, that if when we refer to houses, mountains and rivers we are referring to things we are aware of, and if (as other philosophers agreed) we are aware only of ideas, houses, mountains and rivers must *be* 'ideas' or appearances or, better, 'collections' of such ideas. Certainly – and this was one thing that his readers found most difficult to handle, but which Berkeley himself was most insistent on – there is no need to deny that houses, mountains and rivers exist, but only to stress (common-sensibly) that they are the very things we perceive, which is to say that they are mind-dependent ideas. Their *esse* (being) is *percipi* (to be perceived); they exist only in the mind.

Berkeley's major philosophical works, and in particular the *Principles* and *Dialogues*, are, in the main, a sustained defence of these insights and doctrines, together with a working out of their implications. For Berkeley, the implications, including those for religion and the sciences, are as important as the basic metaphysics. Yet the fundamental case for that metaphysics is supposed to be very simple indeed. Even by the end of section six of the *Principles* (under three pages in most editions) that case has supposedly been established.

4 The New Theory of Vision

Although Berkeley's *An Essay towards a New Theory of Vision* (1709) was published just one year before the *Principles*, and Berkeley was already convinced that there was no such thing as 'matter', or bodies 'without the mind', this, his first major work, stopped short of making that claim. As he said in the *Principles*, although the earlier book had shown that 'the proper objects *of sight* neither exist without the mind, nor are the images of external things (*Principles* §44; emphasis added), it had done nothing to disabuse readers of the view that tangible objects are external. At one level, then, the work can be seen as a sort of halfway house on the route to presenting his full case for immaterialism, but it is undoubtedly also true that he was fascinated by problems concerning vision in their own right. He was clearly very well read in optical theory, he had his own highly distinctive contribution to make, and for many years that contribution was esteemed by many who had little interest in, or were possibly quite blind to, any wider implications it may have had.

Ostensibly, then, the *New Theory of Vision* is merely an attempt to 'shew the manner wherein we perceive by sight the distance, magnitude, and situation of objects', though, still in the opening section, Berkeley also announces that he will be considering 'the difference there is betwixt the ideas of sight and touch, and whether there be any idea common to both senses' (*New Theory of Vision* §1). Broadly, the issue concerning 'situation', which others had recognized, is that of how we see things the 'right' way up (so to speak) when their images are inverted on the retina; that concerning 'magnitude' is how we judge objects at a distance to be small or large (one particular problem was why the moon on the horizon looks larger than the moon in the zenith, although they are virtually the

same distance from us); and that concerning 'outness' or distance is that of how we come to see things as being at various distances, given that, as Berkeley observes, it was accepted that 'distance being a line directed end-wise to the eye, it projects only one point in the fund of the eye, which point remains invariably the same, whether the distance be longer or shorter' (*New Theory of Vision* §2). Berkeley's solution is similar in each case. In the case of distance, for example, even when an object is relatively close, we do not, as others had supposed, make our judgments on the basis of what Descartes had described as a sort of 'natural geometry', and on facts such as that lines drawn from the two eyes to the object form a greater angle the closer the object is: the supposed lines and angles are only theoretical entities, and are not at any rate perceived. Rather, we *learn* to make these judgments solely on the strength of certain sensory cues including, for example, the sensations accompanying the turn of the eyes, and the increasingly confused appearance of an object as it comes closer to us. An explanation in terms of geometry is thus replaced by a psychology of vision in which, crucially, the connection between the cues and the distance discoverable by touch turns out to be purely contingent. '[I]f it had been the ordinary course of Nature that the farther off an object were placed, the more confused it should appear, it is certain the very same perception that now makes us think an object approaches would then have made us to imagine it went farther off' (*New Theory of Vision* §26).

Though often regarded as controversial, Berkeley's work on the psychology of vision was also highly influential even though, and indeed partly because, Berkeley's ultimate metaphysical commitments are not apparent, and certainly not necessarily required for an acceptance, for example, that 'a man born blind, being made to see, would at first have no idea of distance by sight'. Admittedly Berkeley's account of our judgments is in terms of 'sensations', 'appearances' and 'ideas', as all we have to go on, and we are told, for example, not only that the man just cured of blindness would take the 'objects intromitted by sight' to be 'no other than a new set of thoughts or sensations, each whereof is as near to him as the perceptions of pain or pleasure, or the most inward passions of his soul', but that he would be right to do so (*New Theory of Vision* §41). Yet nothing is said to disabuse the reader of the thought that there is, for example, a distant moon, which is not at all dependent on the mind. There is a sense, therefore, in which the *New Theory of Vision* offers us some of the fruits of idealism without explicitly announcing the immaterialism, and one of those fruits is an indication of the existence of God (see IDEALISM). By the end of the work, Berkeley has concluded that there are no ideas common to sight and touch: the extension perceived by touch, for example, is quite distinct from, and has no likeness to, any visual idea. Here he considers a problem first raised by William Molyneux and discussed by Locke, agreeing with them that a man just cured of blindness who saw a cube and a globe for the first time would not know just by looking which was which, but seeing this answer as confirming his own view that visual ideas are merely 'signs'. These we learn to correlate with tangible ideas in much the same way as we learn a language. Berkeley takes this analogy very seriously. His conclusion in the first edition is thus that 'the proper objects of vision constitute the universal language of nature, whereby we are instructed how to regulate our actions', but by the third edition 'nature' has become 'the Author of nature', or God (*New Theory of Vision* §147).

5 *The Introduction to the* Principles

Berkeley prefaces *A Treatise concerning the Principles of Human Knowledge* (1710) with an important introduction which is for the most part devoted to an attack on abstract ideas, and in particular abstract general ideas. In it he quotes freely from Locke. Yet, as already stated, his target was wider, including philosophers generally and, ultimately, a variety of philosophical confusions. One needs to look outside the introduction to discover what these alleged confusions are. Sometimes this is fairly straightforward. Even in the *New Theory of Vision* the notion that there is an idea of extension common to both sight and touch is ascribed to the supposition that we can abstract it from all other visible and tangible qualities; while, in the *Principles*, the notion that the supposed 'primary' qualities exist in the outward object, although colours and the like are 'in the mind alone', is undermined by the observation that 'extension, figure, and motion, abstracted from all other qualities, are inconceivable'. Similarly, the idea of 'pure' or 'absolute' space is ruled out, it being 'a most abstract idea'. In one important case the connection is perhaps less obvious: Berkeley claims that holding that sensible objects can exist unperceived depends on illegitimate abstraction, but commentators have often found it difficult to see precisely how this is supposed to work. In yet other cases, the supposed connections have been less frequently explored in the literature, as for example when Berkeley has it that the Schoolmen were 'masters of abstraction' and, in the *Dialogues*, that Malebranche 'builds on the most abstract general ideas'. These matters can probably be sorted out. Malebranche had attacked the 'disordered abstractions' of the Schoolmen, who posited occult

qualities and powers, and who supposed that matter is something distinct from its known attributes, and in particular from extension, and Berkeley had probably learned from that. Yet Malebranche himself fell foul of Berkeley's anti-abstractionism by talking of 'absolute' and 'intelligible' extension, by supposing that extension was the essence of matter, and by assuming an idea of 'being in general'. The connection between abstraction and the denial of the '*esse* is *percipi*' principle is trickier.

Berkeley's introduction attacks the view that, although the qualities of objects are always 'blended together' in them, we can frame a separate idea of each quality; that we can form, for example, an abstract idea of colour or extension in general; and that we can frame an idea corresponding to the word 'man' or 'triangle', as distinct from the ideas of particular men or particular triangles, as Locke had suggested. This in turn requires from Berkeley an alternative account of language to Locke's, which will not require that each general term stands for an idea. This alternative account is not worked out very fully, but Berkeley does insist that 'a word becomes general by being made the sign, not of an abstract general idea but, of several particular ideas, any one of which it indifferently suggests to the mind' (*Principles*, Intro. §11). Moreover, suggestions towards the end of the introduction that words have other uses than to mark out ideas, including the production of appropriate emotions – 'May we not, for example, be affected with the promise of a *good thing*, though we have not an idea of what it is?' (*Principles*, Intro. §20) – have rightly been seen as significant, and further developments along these lines, in particular in the seventh dialogue of *Alciphron*, have even been seen as making him a precursor of WITTGENSTEIN in this area.

6 *The* Principles

Berkeley's basic metaphysical position is usually known as 'idealism' or, because of what it denies, as 'immaterialism', and the classic defence of this position is offered in *A Treatise Concerning the Principles of Human Knowledge*. Like all Berkeley's works, this is well structured, with just 156 short sections: sections 1–33 argue the case for his idealism, sections 34–84 anticipate and answer possible objections, and the remaining sections take 'a view of our tenets in their consequences'.

As already indicated, Berkeley takes even his opponents to accept that, whatever else there may turn out to be in the world, we perceive only ideas. This assumption emerges in the opening section of the *Principles* (which is clearly modelled on the opening sections of the first chapter of Book II of Locke's *Essay*). Here Berkeley writes, or at least suggests, that 'the objects of human knowledge' are all 'ideas', adding that when certain ideas, for example a certain colour, smell and so on are found going together they are 'reputed as one thing'. On the face of it, this blurs Locke's distinction between 'qualities' and 'ideas', and ignores Locke's supposition of a 'substratum' for the qualities. Yet Berkeley knows what he is doing, and clearly found encouragement in Locke's own preparedness not only to use 'idea' where he means 'quality', but also to assert that we have no other ideas of particular sorts of substances 'than that which is framed by a collection of those simple *ideas* which are to be found in them'. Certainly, we are supposed to start with 'ideas', although – as Berkeley points out in the second section – there are also the minds or spirits that perceive them. However, he soon insists that there can be no substance apart from mind. Given that sensible objects are ideas, and that ideas exist only when perceived, it becomes simply absurd to suppose that these objects could have any existence apart from perception; a fact that is confirmed, in Berkeley's view, simply by attending to 'what is meant by the term *exist* when applied to sensible things'. When I say that a table 'exists', I am referring to something that I perceive, or at least that I might perceive, and certainly not applying 'exists' to some object which, because it is not an idea, is not perceived at all.

This argument, like most of Berkeley's arguments, is tricky and needs careful handling. Ostensibly, it seems to have very little to do with the word 'exists' because, as Andrew Baxter observed, neither philosophers nor ordinary people seem to mean 'is perceived' by 'exists' in sentences such as 'the table exists'. That point is a fair one, and Berkeley's actual argument does seem to depend heavily on the underlying assumption that the only perceivable objects are mind-dependent items, which must consequently be actually perceived. The stress put on the word 'exists' remains puzzling, however, and one relevant fact seems to be that Locke had held that 'existence' was a simple idea 'suggested to the Understanding, by every Object without, and every *Idea* within' (Locke, *Essay,* II 7: §7). Berkeley had convinced himself both that the idea thus described was abstract (and hence impossible), and that this idea is involved when people suppose things to exist quite independently of perception. To perceive a table as existing and to simply perceive it are one and the same experience, and the existence cannot be separated from the perception so that we can attribute an 'absolute existence' to the thing.

That is at any rate what Berkeley concludes on the basis of the first few sections. But of course he expected resistance. His tactic now becomes,

therefore, to seize on supposedly unsatisfactory features of his opponents' position and, by exposing them, to further his own case. If it is suggested, for example, that our ideas are merely the *likenesses* of external qualities, the counter is that an idea (or perceived thing) can be *like* nothing but an idea (or another perceivable thing). To those who argue that the supposed 'primary' qualities exist in outward objects but that colours and the like do not, his response is twofold: first, we cannot even conceive of an object having merely extension, figure and motion, but lacking any of the qualities these other philosophers recognize as mind-dependent; second, the basic argument deployed to prove that secondary qualities are mind-dependent (that is, that the appearance varies in varying circumstances) would prove the same of any quality whatsoever. Furthermore, those who posit a material substratum as the *support* of qualities find that they can attach no clear meaning in this context even to the term 'support'. There are other arguments, including a particularly tricky and much discussed one in which he proudly claims that it is impossible to conceive that there even *might* be a mind-independent object, for to conceive it would be to frame the idea of it, which would mean that it was an object of thought or perception after all. However, Berkeley is at his rumbustious best in sections 18–20, arguing that neither sense nor reason can establish that there are external bodies, and that they cannot even be posited as an hypothesis to account for our receiving the ideas we do. Even if we suppose, arbitrarily, that there are external bodies, the materialists 'by their own confession are never the nearer knowing how our ideas are produced: since they own themselves unable to comprehend in what manner body can act upon spirit, or how it is possible it should imprint any idea in the mind' (*Principles* §19). What emerges, predictably, is that the only possible cause of our ideas is another, superior spirit, who presents our ideas to us in orderly ways which in fact *constitute* the Laws of Nature, and which Berkeley also sees as constituting the *language* of God himself.

7 *The* Principles *(cont.)*

While the first thirty-three sections of the *Principles* are in an obvious sense basic, the sections in which Berkeley deals with possible objections to his thesis are important too. Here most readers new to Berkeley are likely to find that the first objections that spring to their minds have been anticipated, while the answers Berkeley gives help to clarify his basic thesis. The objections he envisages include, for example, that, given his idealism, everything becomes illusory or unreal; that we see things at a distance from us, so they are not 'in the mind'; that, if the *esse* of sensible things is *percipi*, they will disappear when we stop perceiving them, which is absurd; and that, if objects are only ideas, or collections of ideas, there can be no causal interaction between them, so we will have to deny that fire heats and that water cools. Whether Berkeley's answers to such objections satisfy us is another matter, but the objections are at least confronted, and the answers are always interesting. On the third objection mentioned above, for example, it is eventually suggested that for an object to exist it is necessary only for some mind to perceive it, with the implication that God's perception may guarantee the continued existence of objects. The answer to the fourth objection above is that, just as we continue to say that the sun 'rises' despite scientific knowledge that it is the earth that moves, so this is another area where 'we ought to *think with the learned, and speak with the vulgar*' (*Principles* §51), recognizing that, strictly, the regularities in nature we describe as causal are ultimately down to God. In answering both these objections, Berkeley is typically quick to point out that his philosophical opponents are insecurely placed to make them. Even those who hold that there are external and material bodies are committed to the view that light and colours, or visible objects, are 'mere sensations', and thus to holding that these disappear when I shut my eyes; while, when it comes to causal relationships between objects, many other philosophers, both among the Schoolmen and modern philosophers, have held that God is the 'immediate efficient cause of all things'.

In answering the second of the above objections, Berkeley predictably refers the reader back to the *New Theory of Vision*; but his answer to the first objection is more complex. There are, he stresses, decisive differences between the 'faint, weak, and unsteady' ideas of the imagination and those imprinted on the senses by God, and though he calls both 'ideas' to emphasize that they are equally in the mind, he would not object to simply calling the latter 'things'. Nor does he deny even that there are corporeal substances, if 'substance' is taken 'in the vulgar sense, for a combination of sensible qualities'. It is, he suggests, only other *philosophers* he opposes, for they take corporeal substance to be 'the support of accidents or qualities without the mind'. We may well feel that this point glosses over the one big difference between Berkeley and the vulgar, which is that the vulgar do not recognize sensible qualities to be mind-dependent ideas, but it is one that Berkeley insists on. 'The only thing whose existence we deny, is that which philosophers call matter or corporeal substance. And in doing of this,

there is no damage done to the rest of mankind, who, I dare say, will never miss it' (*Principles* §35).

8 *The* Principles *(cont.)*

The full title of the *Principles* describes it as a work 'Wherein the chief causes of error and difficulty in the Sciences, with the grounds of Scepticism, Atheism, and Irreligion, are inquired into'. While Berkeley believes idealism to be true, he is as interested in the benefits that flow from accepting it. These include establishing the existence of God and attaining a proper understanding of God's role in the world; the banishment of scepticism concerning the nature and the very existence of 'real' things, both of which result from distinguishing the 'real' from what we perceive; and the resolution of certain philosophical, scientific and mathematical perplexities. From section 85 onwards, therefore, Berkeley takes 'a view of our tenets in their consequences'.

Some of the supposed advantages are obvious once stated, and they include the resolution of three issues Berkeley mentions at the outset: 'Whether corporeal substance can think?' (a possibility mooted by Locke, which threatened belief in the natural immortality of the soul); 'Whether matter be infinitely divisible?' (a long-standing issue, with Bayle in particular having exposed the paradoxes that arise whether we suppose that it is or it is not); and 'how [matter] operates on spirit?' (a problem that had exercised the Cartesians). None of these questions arises once it has been proved that there is no 'matter'; that the soul is immaterial, or 'one simple, undivided, active being' which is therefore 'indissoluble by the force of Nature'; and that, just as we can produce ideas in our own minds when exercising our fancies, so God (the superior spirit) can produce in our minds those ideas which constitute sensible things. In addition, however, Berkeley explores at some length the implications for natural philosophy and mathematics.

These, it must be stressed, were not simply casual interests for Berkeley. His very first publication – a compilation of two titles, *Arithmetica* and *Miscellanea Mathematica*, (1707) – evidences his early proficiency in mathematics, and the philosophically more significant manuscript *Of Infinites* was written at about the same time. The latter concentrates on the 'disputes and scruples' which infect modern analytical geometry, all arising from 'the use that is made of quantitys infinitely small'. Moreover *De Motu* (1721) includes an examination of the role that such concepts as force, gravitation and attraction play in Newtonian mechanics. There would have been more on these topics in the additional parts of the *Principles* which Berkeley intended to write, as indeed there would have been on persons, perceivers or spirits. What he does say on the latter subject in the *Principles* as we have it is thin, and it is perhaps necessary only to note that Berkeley's view is indeed broadly Cartesian, though the Berkeleian dualism is between 'indivisible, incorporeal, unextended' minds and ideas, not minds and 'matter'; that he even convinces himself that the soul always thinks; and that the stress is on Berkeley's claim that we do not know ourselves, or other spirits, by way of *idea*. This insistence underlies our earlier observation that in the opening section of the *Principles* Berkeley writes, or at least *suggests*, that all the objects of knowledge are ideas; for the truth is that, though Berkeley was prepared to give this impression at the outset (presumably so as not to raise an unnecessary complication early on), his own use of 'idea' for 'any sensible or imaginable thing', as he put it in the *Philosophical Commentaries*, rules out any 'idea' of spirit, or of the operations of the mind. Certainly, though, this is not supposed to be worrying, and Berkeley is not suggesting that the word 'mind' is insignificant. When he started penning the entries in the *Commentaries* he had indeed accepted the Lockian view that all significant words stand for ideas, but he had soon rejected that principle, partly as a result of deciding that the essentially active mind must be carefully distinguished from its passive objects or 'ideas'.

9 Three Dialogues between Hylas and Philonous

The *Principles of Human Knowledge* is the most important book in the Berkeleian corpus and, had its reception not been so disappointing to Berkeley, the *Three Dialogues between Hylas and Philonous* (1713) would probably not have been written. People were readier to ridicule than to read a treatise that denied the existence of 'matter', while those who did read it usually misunderstood it. The *Dialogues*, therefore, were written, as Berkeley says in the preface, 'to treat more clearly and fully of certain principles laid down in the First [Part of the *Principles*], and to place them in a new light', and the dialogue form proved an admirable way of allowing likely objections to be dealt with at each stage (as well as making the book still perhaps the most attractive introduction to Berkeley). The protagonists are Hylas (the name derives from the Greek word for 'matter') and Philonous (the 'lover of mind', representing Berkeley himself). At the outset Hylas assumes that the Berkeleian is the proponent of 'the most extravagant opinion that ever entered into the mind of man' (*Works*, vol. 2: 172), but, as the discussion progresses, Philonous is able to demonstrate that, although he accepts with other philosophers that 'the things immediately perceived,

are ideas which exist only in the mind', his additional acceptance of the view of ordinary men and women that 'those things they immediately perceive are the real things' allies him with common sense (*Works*, vol. 2: 262).

Doctrinally there are no substantial innovations here, although Berkeley has Philonous take pains early on to convince Hylas that 'sensible qualities', or the things *immediately* perceived, are mind-dependent, making great play of how appearances vary for different perceivers, and for the same perceiver in different circumstances. Other features include a striking passage, expanded in the third edition, which contains an anticipation of, and an attempt to answer, what is normally taken to be the Humean point that material and spiritual substance are on a par, so that if one is rejected, so too should the other. It is indeed a particularly attractive feature of the work that Hylas is allowed to be a quite pugnacious opponent who really does test the idealist's position. To give just one other instance, it is likely to occur to us that, if the things we perceive are identified with 'ideas' or 'sensations', surely each idea will be dependent on the particular mind that has or perceives it, with the apparently far from common-sense consequence that 'no two can see the same thing'. Berkeley's answer may or (more likely) may not satisfy us, but there is a deeper issue underlying Hylas' challenge which Berkeley himself may not have adequately explored. This concerns the relationship between particular ideas – whether described as 'sensations' or 'appearances' – and the 'collections' of ideas which, for Berkeley, constitute publicly observable objects. There are no more than hints that Berkeley may be prepared to countenance the notion that the permanently existent table is an archetypal idea in God's mind, and that we can be said to perceive it when we perceive any of the 'fleeting . . . and changeable ideas' which, to some degree, correspond to it.

10 De Motu

Berkeley intended to publish additional parts of the *Principles* and apparently made some progress on the second part, telling Samuel Johnson in 1729 that 'the manuscript was lost about fourteen years ago, during my travels in Italy, and I never had leisure since to do so disagreeable a thing as writing twice on the same subject', but that was as far as he got. Remarks in the *Philosophical Commentaries* suggest that one part would have been 'our Principles of Natural Philosophy', and we can assume that it would have included the sort of material covered in a work he did publish, *De Motu* (1721). This work reiterates and develops certain points already made in the *Principles* when Berkeley was taking 'a view of our tenets in their consequences', but although it is indeed assumed that minds are not corporeal, it would not have been apparent to the reader that Berkeley holds that the *esse* of sensible things is *percipi*. Rather, what is insisted on is that 'it is idle to adduce things which are neither evident to the senses, nor intelligible to reason' (*De Motu* §21), and that when we attribute gravity and force to bodies we are improperly positing occult qualities which take us beyond anything we can experience or conceive. 'Abstract terms (however useful they may be in argument) should be discarded in meditation, and the mind should be fixed on the particular and the concrete, that is, on the things themselves' (*De Motu* §4).

It is, therefore, idle to look to the qualities of bodies themselves in order to discover a cause of motion, for 'what we know in body is agreed not to be the principle of motion' (*De Motu* §24). Relying as we should on what we can conceive, we must look to mind for that principle, for we know from our ability to move our limbs that minds can act. On this basis we should conclude that 'all the bodies of this mundane system are moved by Almighty Mind according to certain and constant reason' (*De Motu* §32).

It is clear, then, that *De Motu* fits in with Berkeley's ultimate aim in all his philosophical writings, which is to bring out the dependence of the world upon God. Yet here, as in the case of everything he was to publish later, the elements of his metaphysics that had most perplexed the readers of the *Principles* and the *Dialogues* are either absent or in the background. Indeed, it is a feature of *De Motu* that Berkeley is anxious to present himself as representing a tradition going back to the ancient Greeks, but including the Schoolmen and the Cartesians, which recognizes the ultimate dependence of motion on God. Indeed, 'Newton everywhere frankly intimates that not only did motion originate from God, but that still the mundane system is moved by the same actus' (*De Motu* §32). It must be stressed, however, that it is not this supposed consensus that makes Berkeley's philosophy of science interesting, but his understanding of the proper role of the natural scientist as contrasted with that of the metaphysician. Terms such as 'gravity' and 'force', for example, have a legitimate use, in facilitating calculations on the basis of certain observable regularities in the behaviour of objects. We go wrong only if we confuse the discovery of regularities with genuine explanations of them. By contrast, absolute space and absolute motion, which were posited in Newtonian mechanics, are rejected outright, as indeed they were in the *Principles*. We should 'consider motion as something sensible, or at least

imaginable', and 'be content with relative measures' (*De Motu* §66). If there were but one body in the universe, it would make no sense to suppose that it moved (see NEWTON, I.).

11 Alciphron *and* The Analyst

Berkeley published *De Motu* in 1721 and nothing of any philosophical significance for over ten years thereafter. Indeed none of his later writings matched in importance what had already appeared. Yet all were controversial, and some were taken very seriously at the time. These included *Alciphron* (1732) and *The Analyst* (1734) which represent, if in very different ways, Berkeley's commitment to defending religion against those seeking to undermine it.

Alciphron is composed of seven lively dialogues in which two Christian gentlemen, Euphranor and Crito, defend the religious and Christian standpoint against two 'free-thinkers', Alciphron and Lysicles. These are, of course, fictitious characters, but are allowed on occasion to present (or misrepresent, as many have claimed) the views of such actual, though unnamed, figures as the third Earl of Shaftesbury and Bernard MANDEVILLE. Mandeville complained bitterly that his thesis arguing private vices are public benefits had been totally distorted in *Alciphron*; others have said the same of Berkeley's treatment of Shaftesbury's ethical theory. For all that, the book remains very readable. It contains, moreover, the only account of free will published by Berkeley, and also the first explicit linking of the doctrine concerning the heterogeneity of the objects of sight and touch to a proof of the existence of God. Additionally there is a discussion in the Seventh Dialogue of particular interest in that it returns us to the topic of language.

The context is still the acceptability of religion, but at this point the objection from the free-thinker Alciphron is that the Christian religion is ultimately unacceptable, not because it can be shown to be false, but because it is straightforwardly unintelligible, involving, as it does, such meaningless notions as that of 'grace'. Here Alciphron appeals to the principle that 'words that suggest no ideas are insignificant'. Consequently this principle, which Berkeley had himself assumed in a demonstration of immaterialism nearly halfway through the *Commentaries*, now becomes his explicit target. He reiterates his objection to abstract ideas, but also stresses the role of words in directing our practices, whether in mathematics and natural science, or in the religious sphere. It has been debated whether or not what we find here marks any decided shift from the line he had taken in the introduction to the *Principles*, and it is certainly true that Berkeley had long since moved towards the position he adopts here, but the discussion in *Alciphron* does reflect his mature consideration of the topic. It stresses the use of words as signs which, as he had put it to Samuel Johnson, 'as often terminate in the will as in the understanding, being employed rather to excite, influence, and direct action, than to produce clear and distinct ideas' (*Works*, vol. 2: 293).

By contrast with *Alciphron*, the *Analyst* is a technical work in the philosophy of mathematics, containing criticisms of Newton's calculus. The adequacy of these criticisms is still debated, but they were sufficiently acute to generate considerable controversy among the mathematicians. To this controversy Berkeley contributed two further works in 1735, *A Defence of Free-thinking in Mathematics*, and *Reasons for not replying to Mr. Walton's Full Answer*. Berkeley's theological preoccupations are again relevant in this area, for *The Analyst* was addressed to an unnamed 'infidel mathematician', who has generally been identified with Edmund Halley (of Halley's Comet fame). Halley had been reported as claiming that Christian doctrines were 'incomprehensible', and the religion an 'imposture'. Berkeley is able to take delight in answering that the objection comes ill from a mathematician. He targets what he saw as obscurities and contradictions in the calculus. Some of these result from assuming an increment of infinitesimal value which, without reaching zero, proceeds towards a limit of zero, allowing the analyst to predict the system's value at a conceptual point at which the increment becomes nothing. A consequence is that these 'ghosts of departed qualities' are both used and disregarded in one and the same proof. As already mentioned, Berkeley's interest in mathematics was of long standing, as was his opposition to infinitesimal quantities. He was able to show how these lead to absurdities in the calculus, and to argue against those who 'though they shrink at all other mysteries, make no difficulty of their own'. Moreover, he was able to do this without mentioning his own idealist view that, because *esse* is *percipi*, the smallest quantity must be what he had earlier called the *minimum sensibile*, which cannot be divided into parts.

12 Siris

Siris (1744), the last of Berkeley's writings of any substance, is also in many ways the strangest. His championship of tar-water as a useful remedy against many diseases (and as a possible panacea) is likely to strike us as foolish, though it was to some extent understandable given his apparently successful use of it in his diocese. Moreover, although it was practical experience that had led him to his belief in the virtues of tar-water, Berkeley does go deeply into the explanation of its effectiveness,

relying on theories which gave prominence to the role of 'aether', or 'pure invisible fire', as the vital principle of the corporeal world. Here again we can now see that Berkeley was wrong, although he was able to appeal to authorities, both ancient and modern. Indeed, this readiness to appeal to authorities, or to seek for maximum consensus, extends to the final sections in which his chain of philosophical reflections leads him to focus on God as 'the First Mover, invisible, incorporeal, unextended, intellectual source of life and being' (*Siris* §296). Here themes familiar from the early works re-emerge – including the view that 'all phenomena are, to speak truly, appearances in the soul or mind' (*Siris* §251) and that there are, strictly, no corporeal causes. Yet these are now tied in with what appear to be alien elements. There is a tendency to disparage the senses, and Berkeley's fascination with the philosophies of the ancients extends to a degree of sympathy for the Platonic Theory of Forms. That said, Berkeley's eclectic and somewhat hesitant approach in *Siris* is such that it would be wrong to look to it for evidence of a substantially new philosophical position. Though fascinating in its way, *Siris* now seems very dated indeed.

13 Concluding remarks

Inevitably, Berkeley is famed for the metaphysics of the *Principles*, and *Dialogues*. It would be easy to multiply quotations from people who treated this metaphysics as absurd, but very wrong to suggest that all the reactions have been hostile, or that the more hostile responses have not frequently been based on misunderstandings. At the other extreme, John Stuart Mill was to refer to Plato, Locke and Kant among others when describing Berkeley as 'the one of greatest philosophic genius' (Mill 1871: 'Berkley's Life and Writings'), while A.A. Luce, the most prominent Berkeley scholar of the twentieth century, held Berkeley's views to be fundamentally correct, and to coincide with the common-sense view of the world. Even many who would be less effusive have at least seen Berkeley as playing an important role in the history of philosophy, if only as marking one important stage on the route from Locke to Hume, and then to Kant and modern idealism. Certainly, no serious commentators would judge that his views can be easily or simply dismissed, though they would often give very different accounts of what makes him important and interesting. Luce, for example, found the role God has to play in Berkeley's system attractive; Mill thought it an embarrassment. Phenomenalism, the theory of perception which Mill himself espoused, could indeed be described as 'Berkeley without God' (see Mill, J.S. §6; Phenomenalism).

The fact is that Berkeley was grappling with problems that are perennial in philosophy, including that of the relationship between appearance and reality, or between our experiences and what we take them to be experiences of. Their treatments of these issues have very often led philosophers to say things that would strike the 'vulgar' as strange, and if Locke's position, for example, seems initially more congenial (in that Locke never doubts the existence of a world corresponding to, but distinct from, our 'ideas', and treats scepticism in that area as absurd), Berkeley was neither the first nor the last to see him as, in effect, making knowledge of that world impossible. Berkeley did not invent the sceptical challenge that arises from insisting on a distinction between what we 'immediately' perceive and an external 'material' world; if his way of dealing with it is radical, one must recognize that 'idealism' in one form or another was to have quite a history – even now there are philosophers who are happy to use the label to describe their own philosophical positions.

Certainly Berkeley does sometimes exaggerate the extent to which he is at one with the 'vulgar', or with our ordinary views about the world. He may be quite right that he is at one with those who believe that '*those things they immediately perceive are the real things*'. Yet, as we saw in §9 above, it is only by combining this with the claim that '*the things immediately perceived, are ideas which exist only in the mind*', which he attributes to 'the philosophers', that he arrives at a theory concerning the nature of reality that is very much his own. Consequently, although he can chide his opponents for their commitment to such views as 'the Wall is not white, the fire is not hot', remarking in the *Commentaries* (entry 392) that 'We Irish men cannot attain to these truths', many of his own claims, such as that 'Strictly speaking . . . we do not see the same object that we feel; neither is the same object perceived by the microscope, which was by the naked eye' (*Works*, vol. 2: 245), would strike the vulgar as equally odd. Berkeley's beliefs about what it is that we 'immediately' perceive may or may not be true, but clearly they are not vulgar views.

To be fair, Berkeley was not unaware that this was the position. For example, his comment that on the issue of causal relationships between objects we should '*think with the learned, and speak with the vulgar*' (*Principles* §51) suggests that the vulgar have not appreciated the truth of the matter; while claims that he opposes only other philosophers contrast with passages such as that in the *Principles* in which he actually refers to the 'mistake' of the vulgar who believe that the 'objects of perception [have] an existence independent of, and without the mind' (*Principles* §56). To be sure, in the same discussion he

suggests that they cannot *really* believe this, because the supposed belief involves a contradiction, and 'Strictly speaking, to believe that which involves a contradiction, or has no meaning in it, is impossible' (*Principles* §54). The whole passage rests on the equation of the objects of perception with 'ideas', which is what *makes* the supposed belief contradictory.

The truth is, therefore, that for all his resolve in the *Commentaries* (entry 751) 'To be eternally banishing Metaphisics &c & recalling Men to Common Sense' (and what he seems to have in mind there is the arid metaphysics of the Schools), Berkeley does offer us what we would naturally describe as a metaphysics, and one that cannot be refuted simply on the ground that it might strike the average person as outrageous. His arguments must be examined on their merits, together with any underlying assumptions; attention has to be paid to the notion of 'immediate' perception which he works with; and account must be taken of possible problems generated by his metaphysical conclusions. These may include, as has often been claimed, an unrecognized tendency towards solipsism. Not that it is necessary to reject or accept his philosophy in total, for there may be insights alongside what we believe are mistakes. As with any philosopher of Berkeley's stature, doing justice to Berkeley's philosophy turns out to be a very complex, but also a rewarding exercise, which is why his philosophy still exercises the commentators today.

The philosophical correspondence between Berkeley and Samuel Johnson is in vol. 2.)

Berman, D. (ed.) (1989) *George Berkeley: Eighteenth-Century Responses*, New York: Garland Publishing, 2 vols. (Contains many of the early responses to various of Berkeley's works. These include some from important or influential figures such as James Beattie and Thomas Reid, the first reviews of the *Principles* and *Dialogues*, and materials not easily accessible elsewhere.)

IAN TIPTON

BERLIN, ISAIAH (1909–97)

Berlin said that he decided about 1945 to give up philosophy, in which he had worked up to that time, in favour of the history of ideas. Some of his best-known work certainly belongs to the history of ideas, but he continued in fact both to write philosophy and to pursue philosophical questions in his historical work.

His main philosophical contributions are to political philosophy and specifically to the theory of liberalism. He emphasizes a distinction between 'negative' and 'positive' concepts of liberty: the former is a Hobbesian idea of absence of constraint or obstacle, while the latter is identified with a notion of moral self-government, expressed for instance in Rousseau, which Berlin finds politically threatening. His anti-utopian approach to politics is expressed also in his view that values necessarily conflict; this irreducible 'value pluralism' may be his most original contribution to philosophy, though he advances it through example and historical illustration rather than in semantic or epistemological terms. He also expresses himself against necessitarian interpretations of history, and in favour of an anti-determinist conception of free will.

BERNARD WILLIAMS

BIOETHICS

While bioethics, a part of applied ethics, is usually identified with medical ethics, in its broadest sense it is the study of the moral, social and political problems that arise out of biology and the life sciences generally and involve, either directly or indirectly, human wellbeing. Thus, environmental and animal ethics are sometimes included within it. In this regard, bioethics can be of broader concern than is either medical/biomedical ethics or the study of the moral problems that arise out of new developments in medical technology.

The interrelated issues of who or what has moral status, of what justifies a certain kind of treatment of one creature as opposed to another, and whether, if a creature has moral status, it can lose it, have proved especially important issues in this broadest sense of bioethics. The philosophical task of probing arguments for soundness appears essential to deciding these issues.

As a part of applied ethics, bioethics is exposed to the difficulty that (1) we do not agree in our moral convictions and principles about many of the cases that feature in bioethics, (2) we do not agree in the moral theories in which our moral principles find their home and by which we try to justify them, and (3) we do not agree in the test(s) of adequacy by which to resolve the disagreements at the level of

moral theory. We seem left with no way of deciding between contending principles and theories.

BLACKSTONE, WILLIAM (1723–80)

Blackstone produced the first systematic exposition of English law as a body of principles. His enterprise was founded upon the assumption that the detailed rules of English law embodied and enforced natural law. Blackstone's invocation of natural law has frequently been regarded as ornamental rather than substantial, but there is no good reason for taking this view. Blackstone is now remembered as much for Bentham's attacks upon him as for his own contribution.

N.E. SIMMONDS

BLOCH, ERNST SIMON (1885–1977)

Bloch was one of the most innovative Marxist philosophers of the twentieth century. His metaphysical and ontological concerns, combined with a self-conscious utopianism, distanced him from much mainstream Marxist thought. He was sympathetic to the classical philosophical search for fundamental categories, but distinguished earlier static, fixed and closed systems from his own open system, in which he characterized the universe as a changing and unfinished process. Furthermore, his distinctive materialism entailed the rejection of a radical separation of the human and the natural, unlike much twentieth-century Western Marxism. His validation of utopianism was grounded in a distinctive epistemology centred on the processes whereby 'new' material emerges in consciousness. The resulting social theory was sensitive to the many and varied ways in which the utopian impulse emerges, as, for example, in its analysis of the utopian dimension in religion.

VINCENT GEOGHEGAN

BOBBIO, NORBERTO (1909–)

The foremost legal and political theorist in Italy today, Norberto Bobbio founded in the 1940s Italian analytical legal positivism, trying to merge logical positivism and Kelsen's legal positivism. As a political thinker, he defends a synthesis of liberalism and socialism, focusing in particular on the defence of human and civil rights in democratic societies.

PATRIZIA BORSELLINO

BODIN, JEAN (1529/30–96)

Jean Bodin was one of the great universal scholars of the later Renaissance. Despite political distractions, he made major contributions to historiography and the philosophy of history, economic theory, public law and comparative public policy, the sociology of institutions, as well as to religious philosophy, comparative religion and natural philosophy. Among his most celebrated achievements are his theory of sovereignty, which introduced a new dimension to the study of public law, and his Neoplatonist religion, which opened new perspectives on universalism and religious toleration.

Many of these intellectual positions, moreover, were responses, at least in part, to great political issues of the time. Against doctrines of popular sovereignty and the right of resistance put forward in the course of the religious wars, Bodin sought to show that the king of France was absolute. Against the widespread corruption and laxity that weakened and undermined the monarchy, he argued for administrative reform. And against the party that pressed the king to impose religious uniformity, he cautiously supported religious toleration. In all these respects Bodin's thought helped to inform the policies of the early Bourbon dynasty esatblished by Henry IV.

JULIAN H. FRANKLIN

BOEHME, JAKOB (1575–1624)

Boehme was a Lutheran mystic and pantheist. He held that God is the Abyss that is the ground of all things. The will of the Abyss to know itself generates a process that gives rise to nature, which is thus the image of God. Life is characterized by a dualistic struggle between good and evil; only by embracing Christ's love can unity be regained. Boehme was highly regarded by such diverse writers as Law, Newton, Goethe and Hegel.

JEAN-LOUP SEBAN

BOETHIUS, ANICIUS MANLIUS SEVERINUS (*c.*480–525/6)

Boethius was a principal transmitter of classical Greek logic from Aristotle, the Stoics and the Neoplatonists to the schoolmen of the medieval Latin West. His contemporaries were largely unimpressed by his learned activities, and his writings show him to have been a lonely, rather isolated figure in a world where the old Roman aristocrats were struggling to maintain high literary culture in an Italy controlled by barbarous and bibulous Goths, whose taste in music and hairgrease Boethius found painful.

Boethius himself was born into a patrician family in Rome, but was orphaned and raised instead by Q. Aurelius Memmius Symmachus, a rich Christian heir to a distinguished pagan line; Boethius later married the latter's daughter, Rusticiana. As well as Symmachus, Boethius had a small circle of educated friends, including the Roman deacon John (who probably became Pope John I, 523–6), who shared his enthusiasm for logical problems. The Gothic king of Italy at Ravenna, Theoderic, had met high culture during his education at Constantinople and made use of experienced Roman aristocrats as administrators. He employed Boethius to design a sundial for the Burgundian king and also a water-clock, specimens of advanced technology intended to impress a barbarian; he also sent a harpist to Clovis, the Frankish king, no doubt intended to soften the latter's bellicose spirit.

By 507 Boethius had gained the title 'patrician' and received letters addressed to 'your magnitude'. Symmachus was in a position to promote his public career. He was nominated consul for the year 510, a position without political power but of high standing and requiring large disbursements of private wealth; it also carried the perquisite that the consul's name stood on all dated documents for that year. In 522 his two sons were installed as consuls, a promotion that gave their father intense pride and pleasure, and he took up seriously the political post of Master of the Offices. In this capacity, his determination to eliminate corruption earned him numerous enemies among both Goths and his fellow Roman aristocrats. His relations with the courtiers at Ravenna became disastrous.

Boethius' fall came when he rashly defended a senator who had been delated to King Theoderic for conducting treasonable correspondence with persons high in the court of the emperor at Constantinople. There is no improbability in the notion that, along with other Roman aristocrats, Boethius would have preferred to be rid of the crude Goths and to see Theoderic replaced by a ruler congenial to the emperor. His great erudition had aroused fears that he was engaged in occult practices dangerous to the Ravenna dynasty. In 524 or early 525, Boethius was imprisoned at Pavia (Ticinum). Here, while awaiting the execution already decreed against him, he composed his masterpiece, *De consolatione philosophiae* (The Consolation of Philosophy).

De consolatione philosophiae, a bitterly hostile attack on Theoderic prefacing a philosophical discussion of innocent suffering and the problem of evil, must have been smuggled out of prison, no doubt with the aid of gold coins from Rusticiana or Symmachus. In the ninth century, the work captured the imagination of Alcuin at the court of Charlemagne, became a standard textbook in schools and was set on the way to being one of the greatest books of medieval culture, especially popular among laymen.

Boethius' earlier works have been the preserve of more specialized readers, especially those concerned with the history of ancient philosophy. His stated original intention was to educate the West by translating all of Plato and Aristotle into Latin and to supply explanatory commentaries on many of their writings. That was too ambitious. He did not proceed beyond some of the logical works (Organon) of Aristotle, prefaced by a commentary on a Latin translation of Porphyry's *Isagōgē* (Introduction) made in the fourth century by Marius Victorinus, an African teaching in Rome, and then by a second commentary on a translation of the same text made by himself. This commentary underlay the medieval debates on universals. He also wrote a commentary on Aristotle's *Categories* and two commentaries on Aristotle's *De interpretatione*. In addition, Boethius adapted Nicomachus of Gerasa's *Arithmetic* for Latin readers, Nicomachus' introduction to music as a liberal art, a commentary on Cicero's *Topics*, a short treatise 'On Division', important treatises on categorical and hypothetical syllogisms and a further tract on different kinds of 'topic'.

Intricate theological debates between Rome and Constantinople convinced him that a trained logician could contribute clarification, and he composed four theological tractates on the doctrines of the Trinity and the person of Christ, concentrating on logical problems. In addition, a fifth tract became a statement of orthodox belief without much reference to logical implications. The five pieces, or *Opuscula sacra*, became hardly less influential than *De consolatione philosophiae*, especially from the twelfth century onwards. We hear of critics who thought contemporary theologians knew more about Boethius than about the Bible.

HENRY CHADWICK

BOHR, NIELS (1885–1962)

One of the most influential scientists of the twentieth century, the Danish physicist Niels Bohr founded atomic quantum theory and the Copenhagen interpretation of quantum physics. This radical interpretation renounced the possibility of a unified, observer-independent, deterministic description in the microdomain. Bohr's principle of complementarity – the heart of the Copenhagen philosophy – implies that quantum phenomena can only be described by pairs of partial, mutually exclusive, or 'complementary' perspectives. Though simultaneously inapplicable, both perspectives are necessary for the exhaustive description of phenomena. Bohr aspired to generalize complementarity into all fields of knowledge, maintaining that new epistemological insights are obtained by adjoining contrary, seemingly incompatible, viewpoints.

MARA BELLER

BOLZANO, BERNARD (1781–1848)

Bernard Bolzano was a lone forerunner both of analytical philosophy and phenomenology. Born in Prague in the year when Kant's first *Critique* appeared, he became one of the most acute critics both of Kant and of German Idealism. He died in Prague in the same year in which Frege was born; Frege is philosophically closer to him than any other thinker of the nineteenth or twentieth century. Bolzano was the only outstanding proponent of utilitarianism among German-speaking philosophers, and was a creative mathematician whose name is duly remembered in the annals of this discipline. His *Wissenschaftslehre* (*Theory of Science*) of 1837 makes him the greatest logician in the period between Leibniz and Frege. The book was sadly neglected by Bolzano's contemporaries, but rediscovered by Brentano's pupils: Its ontology of propositions and ideas provided Husserl with much of his ammunition in his fight against psychologism and in support of phenomenology, and through Twardowski it also had an impact on the development of logical semantics in the Lwów-Warsaw School.

WOLFGANG KÜNNE

BONAVENTURE (*c.*1217–74)

Bonaventure (John of Fidanza) developed a synthesis of philosophy and theology in which Neoplatonic doctrines are transformed by a Christian framework. Though often remembered for his denunciations of Aristotle, Bonaventure's thought includes some Aristotelian elements. His criticisms of Aristotle were motivated chiefly by his concern that various colleagues, more impressed by Aristotle's work than they had reason to be, were philosophizing with the blindness of pagans instead of the wisdom of Christians.

To Bonaventure, the ultimate goal of human life is happiness, and happiness comes from union with God in the afterlife. If one forgets this goal when philosophizing, the higher purpose of the discipline is frustrated. Philosophical studies can indeed help in attaining happiness, but only if pursued with humility and as part of a morally upright life. In the grander scheme of things, the ascent of the heart is more important than the ascent of the mind.

Bonaventure's later works consistently emphasize that all creation emanates from, reflects and returns to its source. Because the meaning of human life can be understood only from this wider perspective, the general aim is to show an integrated whole hierarchically ordered to God. The structure and symbolism favoured by Bonaventure reflect mystical elements as well. The world, no less than a book, reveals its creator: all visible things represent a higher reality. The theologian must use symbols to reveal this deeper meaning. He must teach especially of Christ, through whom God creates everything that exists and who is the sole medium by which we can return to our creator.

Bonaventure's theory of illumination aims to account for the certitude of human knowledge. He argues that there can be no certain knowledge unless the knower is infallible and what is known cannot change. Because the human mind cannot be entirely infallible through its own power, it needs the cooperation of God, even as it needs God as the source of immutable truths. Sense experience does not suffice, for it cannot reveal that what is true could not possibly be otherwise; so, in Bonaventure's view, the human mind attains certainty about the world only when it understands it in light of the 'eternal reasons' or divine ideas. This illumination from God, while necessary for certainty, ordinarily proceeds without a person's being conscious of it.

BOOLEAN ALGEBRA

Boolean algebra, or the algebra of logic, was devised by the English mathematician George Boole (1815–64) and embodies the first successful application of algebraic methods to logic.

Boole seems to have had several interpretations for his system in mind. In his earlier work he thinks of each of the basic symbols of his 'algebra' as standing for the mental operation of selecting just the objects possessing some given attribute or included in some given class; later he conceives of these symbols as standing for the attributes or classes themselves. In each of these interpretations the basic symbols are conceived as being capable of combination under certain operations: 'multiplication', corresponding to conjunction of attributes or intersection of classes; 'addition', corresponding to (exclusive) disjunction or (disjoint) union; and 'subtraction', corresponding to 'excepting' or difference. He also recognizes that the algebraic laws he proposes are satisfied if the basic symbols are interpreted as taking just the number values 0 and 1.

Boole's ideas have since undergone extensive development, and the resulting concept of Boolean algebra now plays a central role in mathematical logic, probability theory and computer design.

J.L. BELL

BOSANQUET, BERNARD (1848–1923)

One of the most prominent and prolific of the British Idealists of the late nineteenth and early twentieth centuries, Bosanquet ranged across most fields of philosophy, making his main contributions in epistemology, metaphysics, aesthetics and especially political philosophy. He was deeply influenced by Plato and by Hegel. Bosanquet and F.H. Bradley were close on many matters, and each regarded the other as a co-worker; however, Bosanquet was always more Hegelian, less rigorous in argument than Bradley and lacking his sceptical approach. Bosanquet treats knowledge and reality as a single whole, working out the implications in the concrete 'modes of experience' of philosophy, science, morality, art, religion, and social and political life. He is at his best in explaining and developing the thoughts of others, particularly of Hegel, Bradley, Rousseau and T.H. Green.

PETER P. NICHOLSON

BOYLE, ROBERT (1627–91)

Boyle is often remembered for the contributions that he made to the sciences of chemistry and pneumatics. Like other natural philosophers in seventeenth-century England, however, he was a synthetic thinker who sought to advance knowledge in all areas of human concern. An early advocate of experimental methods, he argued that experimentation would not only reveal the hidden processes operative in the world but would also advance the cause of religion. Through the study of nature, experimentalists would come to understand that the intricacy of design manifest in the world must be the result of an omniscient and omnipotent creator.

Boyle's experimental investigations and theological beliefs led him to a conception of the world as a 'cosmic mechanism' comprised of a harmonious set of interrelated processes. He agreed with the leading mechanical philosophers of his day that the corpuscular hypothesis, which explains the causal powers of bodies by reference to the motions of the least parts (corpuscles) of matter, provided the best means for understanding nature. He insisted, however, that these motions and powers could not be known by reasoning alone, but would have to be discovered experimentally.

BRADLEY, FRANCIS HERBERT (1846–1924)

Bradley was the most famous and philosophically the most influential of the British Idealists, who had a marked impact on British philosophy in the later nineteenth and earlier twentieth centuries. They looked for inspiration less to their British predecessors than to Kant and Hegel, though Bradley owed as much to lesser German philosophers such as R.H. Lotze, J.F. Herbart and C. Sigwart.

Bradley is most famous for his metaphysics. He argued that our ordinary conceptions of the world conceal contradictions. His radical alternative can be summarized as a combination of monism (that is, reality is one, there are no real separate things) and absolute idealism (that is, reality is idea, or consists of experience – but not the experience of any one individual, for this is forbidden by the monism). This metaphysics is said to have influenced the poetry of T.S. Eliot. But he also made notable contributions to philosophy of history, to ethics and to the philosophy of logic, especially of a critical kind. His critique of hedonism – the view that the goal of morality is the maximization of pleasure – is still one of the best available. Some of his views on logic, for instance, that the grammatical subject of a sentence may not be what the sentence is really about, became standard through their acceptance by

Bertrand Russell, an acceptance which survived Russell's repudiation of idealist logic and metaphysics around the turn of the century. Russell's and G.E. Moore's subsequent disparaging attacks on Bradley's views signalled the return to dominance in England of pluralist (that is, non-monist) doctrines in the tradition of Hume and J.S. Mill, and, perhaps even more significantly, the replacement in philosophy of Bradley's richly metaphorical literary style and of his confidence in the metaphysician's right to adjudicate on the ultimate truth with something more like plain speaking and a renewed deference to science and mathematics.

Bradley's contemporary reputation was that of the greatest English philosopher of his generation. This status did not long survive his death, and the relative dearth of serious discussion of his work until more general interest revived in the 1970s has meant that the incidental textbook references to some of his most characteristic and significant views, for example, on relations and on truth, are often based on hostile and misleading caricatures.

BRAHMAN

The Sanskrit word *brahman* (neuter) emerged in late Vedic literature and Upaniṣads (900–300 BC) as the name (never pluralized) of the divine reality pervading the universe, knowledge or experience of which is a person's supreme good. The word's earliest usage (often pluralized) is to refer to the verses of the oldest work in Sanskrit (and in any Indo-European language), the *Ṛg Veda* (*c.*1200 BC), which is a compilation of poems and hymns to Indo-European gods. The individual verses of the poems are mantras (*brahmāṇi*), whose proper enunciation in the course of ritual and sacrifice was thought to secure various aims. Thematically, the *Ṛg Veda* and other early Indian literature presents a sense of pervasive divinity. Apparently through an assimilation of the idea of the magic of mantras to the divine immanence theme the word *brahman* assumed its later meaning. In any case, Brahman – the Absolute, the supremely real – became the focus of Indian spirituality and the centre of much metaphysics for almost three thousand years, down to the present day. In the Upaniṣads, which are mystic treatises containing speculation about Brahman's nature and relation to ourselves and the world, the central positions of Vedānta schools emerge, all of which are philosophies of Brahman. But not even in the narrow set of the earliest and most universally accepted Upaniṣads (numbering twelve or thirteen) is there expressed a consistent worldview. Important themes about Brahman may be identified, but there is no overall unity of conception, despite what later exegetes claim. The unity of the early Upaniṣads concerns the premier importance of mystical knowledge or awareness of Brahman (*brahma-vidyā*), not precisely what it is that is to be mystically known. The classical Indian philosophical schools of Vedānta systematized the thought of early Upaniṣads.

STEPHEN H. PHILLIPS

BRENTANO, FRANZ CLEMENS (1838–1917)

Brentano was a philosopher and psychologist who taught at the Universities of Würzburg and Vienna. He made significant contributions to almost every branch of philosophy, notably psychology and philosophy of mind, ontology, ethics and the philosophy of language. He also published several books on the history of philosophy, especially Aristotle, and contended that philosophy proceeds in cycles of advance and decline. He is best known for reintroducing the scholastic concept of intentionality into philosophy and proclaiming it as the characteristic mark of the mental. His teachings, especially those on what he called descriptive psychology, influenced the phenomenological movement in the twentieth century, but because of his concern for precise statement and his sensitivity to the dangers of the undisciplined use of philosophical language, his work also bears affinities to analytic philosophy. His anti-speculative conception of philosophy as a rigorous discipline was furthered by his many brilliant students. Late in life Brentano's philosophy radically changed: he advocated a sparse ontology of physical and mental things (reism), coupled with a linguistic fictionalism stating that all language purportedly referring to non-things can be replaced by language referring only to things.

BRUNO, GIORDANO (1548–1600)

Giordano Bruno was an Italian philosopher of nature and proponent of artificial memory systems who abandoned the Dominican Order and, after a turbulent career in many parts of Europe, was burned to death as a heretic in 1600. Because of his

unhappy end, his support for the Copernican heliocentric hypothesis, and his pronounced anti-Aristotelianism, Bruno has often been hailed as the proponent of a scientific worldview against supposed medieval obscurantism. In fact, he is better interpreted in terms of Neoplatonism and, to a lesser extent, Hermeticism (also called Hermetism). Several of Bruno's later works were devoted to magic; and magic may play some role in his many books on the art of memory. His best-known works are the Italian dialogues he wrote while in England. In these Bruno describes the universe as an animate and infinitely extended unity containing innumerable worlds, each like a great animal with a life of its own. His support of Copernicus in *La Cena de le ceneri* (*The Ash Wednesday Supper*) was related to his belief that a living earth must move, and he specifically rejected any appeal to mere mathematics to prove cosmological hypotheses. His view that the physical world was a union of two substances, Matter and Form, had the consequence that apparent individuals were merely collections of accidents. He identified Form with the World-Soul, but although he saw the universe as permeated by divinity, he also believed in a transcendent God, inaccessible to the human mind. Despite some obvious parallels with both Spinoza and Leibniz, Bruno seems not to have had much direct influence on seventeenth-century thinkers.

E.J. ASHWORTH

BUBER, MARTIN (1878–1965)

Martin Buber covered a range of fields in his writings, from Jewish folklore and fiction, to biblical scholarship and translation, to philosophical anthropology and theology. Above all, however, Buber was a philosopher, in the lay-person's sense of the term: someone who devoted his intellectual energies to contemplating the meaning of life.

Buber's passionate interest in mysticism was reflected in his early philosophical work. However, he later rejected the view that mystical union is the ultimate goal of relation, and developed a philosophy of relation. In the short but enormously influential work, *Ich und Du* (I and Thou). Buber argued that the I emerges only through encountering others, and that the very nature of the I depends on the quality of the relationship with the Other. He described two fundamentally different ways of relating to others: the common mode of 'I–It', in which people and things are experienced as objects, or, in Kantian terms, as 'means to an end'; and the 'I–Thou' mode, in which I do not 'experience' the Other, rather, the Other and I enter into a mutually affirming relation, which is simultaneously a relation with another and a relation with God, the 'eternal Thou'.

Buber acknowledged that necessity of I–It, even in the interpersonal sphere, but lamented its predominance in modern life. Through his scholarly work in philosophy, theology and biblical exegesis, as well as his translation of Scripture and adaptations of Hasidic tales, he sought to reawaken our capacity for I–Thou relations.

BUDDHIST PHILOSOPHY, CHINESE

When Buddhism first entered China from India and Central Asia two thousand years ago, Chinese favourably disposed towards it tended to view it as a part or companion school of the native Chinese Huang–Lao Daoist tradition, a form of Daoism rooted in texts and practices attributed to Huangdi (the Yellow Emperor) and Laozi. Others, less accepting of this 'foreign' incursion from the 'barbarous' Western Countries, viewed Buddhism as an exotic and dangerous challenge to the social and ethical Chinese civil order. For several centuries, these two attitudes formed the crucible within which the Chinese understanding of Buddhism was fashioned, even as more and more missionaries arrived (predominantly from Central Asia) bringing additional texts, concepts, rituals, meditative disciplines and other practices. Buddhists and Daoists borrowed ideas, terminology, disciplines, cosmologies, institutional structures, literary genres and soteric models from each other, sometimes so profusely that today it can be difficult if not impossible at times to determine who was first to introduce a certain idea. Simultaneously, polemical and political attacks from hostile Chinese quarters forced Buddhists to respond with apologia and ultimately reshape Buddhism into something the Chinese would find not only inoffensive, but attractive.

In the fifth century AD, Buddhism began to extricate itself from its quasi-Daoist pigeonhole by clarifying definitive differences between Buddhist and Daoist thought, shedding Daoist vocabulary and literary styles while developing new distinctively Buddhist terminology and genres. Curiously, despite the fact that Mahāyāna Buddhism had few

adherents in Central Asia and was outnumbered by other Buddhist schools in India as well, in China Mahāyāna became the dominant form of Buddhism, so much so that few pejoratives were as stinging to a fellow Buddhist as labelling him 'Hīnayāna' (literally 'Little Vehicle,' a polemical term for non-Mahāyānic forms of Buddhism). By the sixth century, the Chinese had been introduced to a vast array of Buddhist theories and practices representing a wide range of Indian Buddhist schools. As the Chinese struggled to master these doctrines it became evident that, despite the fact that these schools were all supposed to express the One Dharma (Buddha's Teaching), their teachings were not homogenous, and were frequently incommensurate.

By the end of the sixth century, the most pressing issue facing Chinese Buddhists was how to harmonize the disparities between the various teachings. Responses to this issue produced the Sinitic Mahāyāna schools, that is, Buddhist schools that originated in China rather than India. The four Sinitic schools are Tiantai, Huayan, Chan and Pure Land (Jingtu). Issues these schools share in common include Buddha-nature, mind, emptiness, *tathāgatagarbha*, expedient means (*upāya*), overcoming birth and death (*saṃsāra*), and enlightenment.

DAN LUSTHAUS

BUDDHIST PHILOSOPHY, INDIAN

Buddhism was an important ingredient in the philosophical melange of the Indian subcontinent for over a millennium. From an inconspicuous beginning a few centuries before Christ, Buddhist scholasticism gained in strength until it reached a peak of influence and originality in the latter half of the first millennium. Beginning in the eleventh century, Buddhism gradually declined and eventually disappeared from northern India. Although different individual thinkers placed emphasis on different issues, the tendency was for most writers to offer an integrated philosophical system that incorporated ethics, epistemology and metaphysics. Most of the issues addressed by Buddhist philosophers in India stem directly from the teachings attributed to Siddhārtha Gautama, known better through his honorific title, the Buddha.

The central concern of the Buddha was the elimination of unnecessary discontent. His principal insight into this problem was that all dissatisfaction arises because people (and other forms of life as well) foster desires and aversions, which are in turn the consequence of certain misunderstandings about their identity. Discontent can be understood as frustration, or a failure to achieve what one wishes; if one's wishes are generally unrealistic and therefore unattainable, then one will naturally be generally dissatisfied. Since the Buddha saw human frustration as an effect of misunderstandings concerning human nature, it was natural for Buddhist philosophers to attend to questions concerning the true nature of a human being. Since the Buddha himself was held as the paradigm of moral excellence, it was also left to later philosophers to determine what kind of being the Buddha had been. A typical question was whether his example was one that ordinary people could hope to follow, or whether his role was in some way more than that of a teacher who showed other people how to improve themselves.

The Buddha offered criticisms of many views on human nature and virtue and duty held by the teachers of his age. Several of the views that he opposed were based, at least indirectly, on notions incorporated in the Veda, a body of liturgical literature used by the Brahmans in the performance of rituals. Later generations of Buddhists spent much energy in criticizing Brahmanical claims of the supremacy of the Veda; at the same time, Buddhists tended to place their confidence in a combination of experience and reason. The interest in arriving at correct understanding through correct methods of reasoning led to a preoccupation with questions of logic and epistemology, which tended to overshadow all other philosophical concerns during the last five centuries during which Buddhism was an important factor in Indian philosophy.

Since the Buddha saw human frustration as an effect that could be eliminated if its cause were eliminated, it was natural for Buddhist philosophers to focus their attention on a variety of questions concerning causality. How many kinds of cause are there? Can a multiplicity of effects have a single cause? Can a single thing have a multiplicity of causes? How is a potentiality triggered into an actuality? Questions concerning simplicity and complexity, or unity and plurality, figured prominently in Buddhist discussions of what kinds of things in the world are ultimately real. In a tradition that emphasized the principle that all unnecessary human pain and conflict can ultimately be traced to a failure to understand what things in the world are real, it was natural to seek criteria by which one discerns real things from fictions.

RICHARD P. HAYES

BUDDHIST PHILOSOPHY, JAPANESE

Buddhism transformed Japanese culture and in turn was transformed in Japan. Mahāyāna Buddhist thought entered Japan from the East Asian continent as part of a cultural complex that included written language, political institutions, formal iconography and Confucian literature. From its introduction in the sixth century through to the sixteenth century, Japanese Buddhism developed largely by incorporating Chinese Buddhism, accommodating indigenous beliefs and reconciling intersectarian disputes. During the isolationist Tokugawa Period (1600–1868), neo-Confucian philosophy and Dutch science challenged the virtual hegemony of Buddhist ways of thinking, but served more often as alternative and sometimes complementary models than as incompatible paradigms. Only since the reopening of Japan in 1868 has Japanese Buddhist thought seriously attempted to come to terms with early Indian Buddhism, Western thought and Christianity.

Through the centuries, Buddhism gave the Japanese people a way to make sense of life and death, to explain the world and to seek liberation from suffering. When it engaged in theorizing, it did so in pursuit of religious fulfilment rather than of knowledge for its own sake. As an extension of its practical bent, Japanese Buddhist thought often tended to collapse differences between Buddhism and other forms of Japanese religiosity, between this phenomenal world and any absolute realm, and between the means and end of enlightenment. These tendencies are not Japanese in origin, but they extended further in Japan than in other Buddhist countries and partially define the character of Japanese Buddhist philosophy.

In fact, the identity of 'Japanese Buddhist philosophy' blends with almost everything with which we would contrast it. As a development and modification of Chinese traditions, there is no one thing that is uniquely Japanese about it; as a Buddhist tradition, it is characteristically syncretistic, often assimilating Shintō and Confucian philosophy in both its doctrines and practices. Rituals, social practices, political institutions and artistic or literary expressions are as essential as philosophical ideas to Japanese Buddhism.

Disputes about ideas often arose but were seldom settled by force of logical argument. One reason for this is that language was used not predominately in the service of logic but for the direct expression and actualization of reality. Disputants appealed to the authority of Buddhist *sūtras* because these scriptures were thought to manifest a direct understanding of reality. Further, as reality was thought to be all-inclusive, the better position in the dispute would be that which was more comprehensive rather than that which was more consistent but exclusive. Politics and practical consequences did play a role in the settling of disputes, but the ideal of harmony or conformity often prevailed.

The development of Japanese Buddhist philosophy can thus be seen as the unfolding of major themes rather than a series of philosophical positions in dispute. These themes include the role of language in expressing truth; the non-dual nature of absolute and relative, universal and particular; the actualization of liberation in this world, life or body; the equality of beings; and the transcendent non-duality of good and evil.

JOHN C. MARALDO

BUDDHIST PHILOSOPHY, KOREAN

Buddhism was transmitted to the Korean peninsula from China in the middle of the fourth century AD. Korea at this time was divided into three kingdoms: Kokuryô, Paekche and Silla. Both Kokuryô and Paekche accepted Buddhism as a state religion immediately after it was introduced, to Kokuryô in 372 AD and to Paekche in 384 AD. However, it was not until two centuries later that Silla accepted Buddhism as a state religion. This was because Silla was the last of the three kingdoms to become established as a centralized power under the authority of one king.

It is not coincidental that Buddhism was accepted by these three states at the very same time that a strong kingship, independent of the aristocracy, was created. These newly established kingships needed a new ideology with which to rule, separate from the age-old shamanistic tradition which had been honored among the previous loose confederations of tribes. Buddhism fulfilled this need. It became a highly valued tool which kings used shrewdly, not only to provide their societies with a political ideology but to give them a foundation from which to build a viable system of ethics and philosophical thinking. Given this historical legacy, Korean Buddhism came to possess a feature which set it apart from the other East Asian traditions: it became 'state-protection' Buddhism. Although this was not a particularly sophisticated phenomenon on a philosophical level, this feature had a lasting influence on all aspects of Buddhist thought in Korea. In general, Korean Buddhism has followed a course of development more or less parallel to that of the greater East Asian context, although with notably closer ties to China than to Japan. There is no historical evidence which indicates any direct

intellectual transmission from India, Buddhism's birthplace; rather, most of the philosophical development of Buddhism in Korea occurred as Korean monks travelled to China to study and obtain Buddhist texts which had either been written in or translated into Chinese. Despite such close ties to China, however, Korean Buddhism has developed its own identity, distinct from that of its progenitor.

Compared to Indian and Central Asian Buddhism, which developed along clear historical lines, the development of Buddhism in China was largely dependent on the personalities of individual monks, and was thus affected by such factors as their region of origination and the particular texts which they emphasized. Thus, in the process of assimilating Indian Buddhism, the Chinese created and developed a number of widely varying schools of Buddhist thought. In Korea, however, such a diverse number of philosophical traditions was never established. Rather, one of the distinct features of Korean Buddhism has been its preference for incorporating many different perspectives into a single, cohesive body of thought.

SUNGTAEK CHO

BUNDLE THEORY OF MIND

See Mind, bundle theory of

BURIDAN, JOHN (*c.*1300–after 1358)

Unlike most other important philosophers of the scholastic period, John Buridan never entered the theology faculty but spent his entire career as an arts master at the University of Paris. There he distinguished himself primarily as a logician who made numerous additions and refinements to the Parisian tradition of propositional logic. These included the development of a genuinely nominalist semantics, as well as techniques for analyzing propositions containing intentional verbs and paradoxes of self-reference. Even in his writings on metaphysics and natural philosophy, logic is Buridan's preferred vehicle for his nominalistic and naturalistic vision.

Buridan's nominalism is concerned not merely with denying the existence of real universals, but with a commitment to economize on entities, of which real universals are but one superfluous type. Likewise, his representationalist epistemology accounts for the difference between universal and singular cognition by focusing on how the intellect cognizes its object, rather than by looking for some difference in the objects themselves. He differs from other nominalists of the period, however, in his willingness to embrace realism about modes of things to explain certain kinds of physical change.

Underlying Buridan's natural philosophy is his confidence that the world is knowable by us (although not with absolute certainty). His approach to natural science is empirical in the sense that it emphasizes the evidentness of appearances, the reliability of a posteriori modes of reasoning and the application of certain naturalistic models of explanation to a wide range of phenomena. In similar fashion, he locates the will's freedom in our evident ability to defer choice in the face of alternatives whose goodness appears dubious or uncertain.

JACK ZUPKO

BURKE, EDMUND (1729–97)

Edmund Burke's philosophical importance lies in two fields, aesthetics and political theory. His early work on aesthetics, the *Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful* (1757), explored the experiential sources of these two, as he claimed, fundamental responses, relating them respectively to terror at the fear of death and to the love of society.

Active in politics from 1759, and Member of Parliament from 1765, Burke wrote and delivered a number of famous political pamphlets and speeches, on party in politics – *Thoughts on the Causes of the Present Discontents* (1770) – on the crisis with the American colonies – *On Conciliation with America* (1775) – on financial reform and on the reform of British India – *Speech on Mr Fox's East India Bill* (1783). While clearly informed by a reflective political mind, these are, however, *pièces d'occasion*, not political philosophy, and their party political provenance has rendered them suspect to many commentators.

His most powerful and philosophically influential works were written in opposition to the ideas of the French Revolution, in particular *Reflections on the Revolution in France* (1790), which has come to be seen as a definitive articulation of anglophone political conservatism. Here Burke considered the sources and desirability of social continuity, locating these in a suspicion of abstract reason, a disposition to follow custom, and certain institutions – hereditary monarchy, inheritance of property, and social corporations such as an established Church. His *Appeal from the New to the Old Whigs* (1791) insisted on the distinction between the French and Britain's revolution of 1688; while his final works, *Letters on a Regicide Peace* (1795), urged an uncompromising

crusade on behalf of European Christian civilization against its atheist, Jacobin antithesis.

BUSINESS ETHICS

Business ethics is the application of theories of right and wrong to activity within and between commercial enterprises, and between commercial enterprises and their broader environment. It is a wide range of activity, and no brief list can be made of the issues it raises. The safety of working practices; the fairness of recruitment; the transparency of financial accounting; the promptness of payments to suppliers; the degree of permissible aggression between competitors: all come within the range of the subject. So do relations between businesses and consumers, local communities, national governments and ecosystems. Many, but not all, of these issues can be understood to bear on distinct, recognized groups with their own stakes in a business: employees, shareholders, consumers, and so on. The literature of business ethics tends to concentrate on 'stakeholders' – anyone who occupies a role within the business or who belongs to a recognized group outside the business that is affected by its activity – but not in every sort of business. Corporations are often discussed to the exclusion of medium-sized and small enterprises.

Theories of right and wrong in business ethics come from a number of sources. Academic moral philosophy has contributed utilitarianism, Kantianism and Aristotelianism, as well as egoism and social contract theory. There are also theories that originate in organized religion, in the manifestos of political activists, in the thoughts of certain tycoons with an interest in social engineering, and in the writings of management 'gurus'. Recently, business ethics has been affected by the ending of the Cold War, and the breakdown of what were once command economies. These developments have encouraged enthusiasts for the market economy to advocate moral and political ideas consistent with capitalism, and the handing over to private companies of activity in certain countries that has long been reserved for the state.

TOM SORELL

BUTLER, JOSEPH (1692–1752)

Joseph Butler the moral philosopher is in that long line of eighteenth-century thinkers who sought to answer Thomas Hobbes on human nature and moral motivation. Following the Third Earl of Shaftesbury, he rejects any purely egoistic conception of these. Instead, he analyses human nature into parts, of which he notices in detail appetites, affections and passions on the one hand and the principles of self-love, benevolence and conscience on the other. His ethics consists in the main in showing the relation of these parts to each other. They form a hierarchy, ordered in terms of their natural authority, and while such authority can be usurped, as when the particular passions overwhelm self-love and conscience, the system that they constitute, or human nature, is rightly proportioned when each part occupies its rightful place in the ordered hierarchy. Virtue consists in acting in accordance with that ordered, rightly proportioned nature.

As a philosopher of religion, Butler addresses himself critically to the eighteenth-century flowering of deism in Britain. On the whole, the deists allowed that God the Creator existed but rejected the doctrines of natural and, especially, revealed religion. Butler's central tactic against them is to argue, first, that the central theses associated with natural religion, such as a future life, are probable; and second, that the central theses associated with revealed religion, such as miracles, are as probable as those of natural religion. Much turns, therefore, on the success of Butler's case in appealing to what is present in this world as evidence for a future life.

CALVIN, JOHN (1509–64)

John Calvin, French Protestant reformer and theologian, was a minister among Reformed Christians in Geneva and Strasbourg. His *Institutes of the Christian Religion* (first edition 1536) – which follows the broad outline of the Apostles' Creed and is shaped by biblical and patristic thought – is the cornerstone of Reformed theology.

Calvin's religious epistemology links self-knowledge and knowledge of God. He identifies in humans an innate awareness of God, which is supported by the general revelation of God in creation and providence. Because sin has corrupted this innate awareness, Scripture – confirmed by the Holy Spirit – is needed for genuine knowledge of God. Scripture teaches that God created the world out of nothing and sustains every part of it. Humanity, which was created good and with free will, has defaced itself and lost significant freedom due to its fall into sin. Calvin sees Christ the mediator as the fulfilment of the Old Testament offices of prophet, priest and king.

Calvin insists that God justifies sinners on the basis of grace and not works, forgiving their sins and imputing Christ's righteousness to them. Such justification, received by faith, glorifies God and relieves believers' anxiety about their status before God. On the basis of his will alone, God predestines some individuals to eternal life and others to eternal damnation.

Calvin dignifies even ordinary occupations by seeing them as service to God. He recognizes the distinction between civil government and the Church, although he says that government should protect true worship of God and Christians should obey and support their government. Calvin's thought was dominant in non-Lutheran Protestant churches until the eighteenth century and has enjoyed a resurgence since the mid-nineteenth century.

CAMBRIDGE PLATONISM

Cambridge Platonism was an intellectual movement broadly inspired by the Platonic tradition, centred in Cambridge from the 1630s to the 1680s. Its hallmark was a devotion to reason in metaphysics, religion and ethics. The Cambridge Platonists made reason rather than tradition and inspiration their ultimate criterion of knowledge. Their central aim was to reconcile the realms of reason and faith, the new natural philosophy and Christian revelation. Although loyal to the methods and naturalism of the new sciences, they opposed its mechanical model of explanation because it seemed to leave no room for spirit, God and life.

In epistemology the Cambridge Platonists were critics of empiricism and stressed the role of reason in knowledge; they also criticized conventionalism and held that there are essential or natural distinctions between things. In metaphysics they attempted to establish the existence of spirit, God and life in a manner consistent with the naturalism and method of the new sciences. And in ethics the Cambridge Platonists defended moral realism and freedom of the will against the voluntarism and determinism of Hobbes and Calvin. Cambridge Platonism was profoundly influential in the seventeenth and eighteenth centuries. It was the inspiration behind latitudinarianism and ethical rationalism, and many of its ideas were developed by Samuel

Clarke, Isaac Newton and the Third Earl of Shaftesbury.

CAMPANELLA, GIOVANNI DOMENICO

See Campanella, Tommaso

CAMPANELLA, TOMMASO (1568–1639)

Tommaso Campanella was a Counter-Reformation theologian, a Renaissance magus, a prophet, a poet and an astrologer, as well as a philosopher whose speculations assumed encyclopedic proportions. As a late Renaissance philosopher of nature, Campanella is notable for his early, and continuous, opposition to Aristotle. He rejected the fundamental Aristotelian principle of hylomorphism, namely the understanding of all physical substance in terms of form and matter. In its place he appropriated Telesio's understanding of reality in terms of the dialectical principles of heat and cold; and he adopted a form of empiricism found in Telesio's work that included pansensism, the doctrine that all things in nature are endowed with sense. Especially after 1602, Campanella's exposure to Renaissance Platonism also involved him in panpsychism, the view that all reality has a mental aspect. Thus his empiricism came to show a distinctly metaphysical and spiritualistic dimension that transformed his philosophy. At the same time his epistemology embraced a universal doubt and an emphasis on individual self-consciousness that are suggestive of Descartes' views.

Campanella's career as a religious dissident, radical reformer and leader of an apocalyptic movement presents a political radicalism that was oddly associated with more traditional notions of universal monarchy and the need for theocracy. The only one of his numerous writings that receives attention today, *La Città del Sole* (*The City of the Sun*) (composed 1602, but not published until 1623), has come to occupy a prominent place in the literature of utopias though Campanella himself seems to have expected some form of astronomical/apocalyptic realization.

Campanella's naturalism, especially its pansensism and panpsychism, enjoyed some currency in Germany and France during the 1620s, but in the last five years of his life it was emphatically rejected by the intellectual communities headed by Mersenne and Descartes, as well as by Galileo.

JOHN M. HEADLEY

CAMPBELL, NORMAN ROBERT (1880–1949)

Campbell made important contributions to philosophy of science in the 1920s, influenced by Poincaré, Russell and his own work in physics. He produced pioneering analyses of the nature of physical theories and of measurement, but is mainly remembered for requiring a theory, for example, the kinetic theory of gases, to have an 'analogy', that is, an independent interpretation, for example, as laws of motion of a swarm of microscopic particles.

D.H. MELLOR

CAMUS, ALBERT (1913–60)

Albert Camus was awarded the Nobel Prize in 1957 for having 'illuminated the problems of the human conscience in our times'. By mythologizing the experiences of a secular age struggling with an increasingly contested religious tradition, he dramatized the human effort to 'live and create without the aid of eternal values which, temporarily perhaps, are absent or distorted in contemporary Europe' (*Le Mythe de Sisyphe* 1943). Thus the challenge posed by 'the absurd' with which he is so universally identified.

DAVID A. SPRINTZEN

CANTOR, GEORG (1845–1918)

Georg Cantor and set theory belong forever together. Although Dedekind had already introduced the concept of a set and naïve set theory in 1872, it was Cantor who single-handedly created transfinite set theory as a new branch of mathematics. In a series of papers written between 1874 and 1885, he developed the fundamental concepts of abstract set theory and proved the most important of its theorems. Although today set theory is accepted by the majority of scientists as an autonomous branch of mathematics, and perhaps the most fundamental, this was not always the case. Indeed, when Cantor set out to develop his conception of sets and to argue for its acceptance, he initiated an inquiry into the infinite which raised questions that have still not been completely resolved today.

See also: Cantor's theorem; Infinity §§6–7; Paradoxes of set and property; Set theory

ULRICH MAJER

CANTOR'S THEOREM

Cantor's theorem states that the cardinal number ('size') of the set of subsets of any set is greater than the cardinal number of the set itself. So once the

existence of one infinite set has been proved, sets of ever increasing infinite cardinality can be generated. The philosophical interest of this result lies (1) in the foundational role it played in Cantor's work, prior to the axiomatization of set theory, (2) in the similarity between its proof and arguments which lead to the set-theoretic paradoxes, and (3) in controversy between intuitionist and classical mathematicians concerning what exactly its proof proves.

MARY TILES

CARNAP, RUDOLF (1891–1970)

Carnap was one of the most significant philosophers of the twentieth century, and made important contributions to logic, philosophy of science, semantics, modal theory and probability. Viewed as an *enfant terrible* when he achieved fame in the Vienna Circle in the 1930s, Carnap is more accurately seen as one who held together its widely varying viewpoints as a coherent movement. In the 1930s he developed a daring pragmatic conventionalism according to which many traditional philosophical disputes are viewed as the expression of different linguistic frameworks, not genuine disagreements. This distinction between a language (framework) and what can be said within it was central to Carnap's philosophy, reconciling the apparently a priori domains such as logic and mathematics with a thoroughgoing empiricism: basic logical and mathematical commitments partially constitute the choice of language. There is no uniquely correct choice among alternative logics or foundations for mathematics; it is a question of practical expedience, not truth. Thereafter, the logic and mathematics may be taken as true in virtue of that language. The remaining substantive questions, those not settled by the language alone, should be addressed only by empirical means. There is no other source of news. Beyond pure logic and mathematics, Carnap's approach recognized within the sciences commitments aptly called a priori – those not tested straightforwardly by observable evidence, but, rather, presupposed in the gathering and manipulation of evidence. This a priori, too, is relativized to a framework and thus comports well with empiricism. The appropriate attitude towards alternative frameworks would be tolerance, and the appropriate mode of philosophizing the patient task of explicating and working out in detail the consequences of adopting this or that framework. While Carnap worked at this tirelessly and remained tolerant of alternative frameworks, his tolerance was not much imitated nor were his principles well understood and adopted. By the time of his death, philosophers were widely rejecting what they saw as logical empiricism, though often both their arguments and the views offered as improvements had been pioneered by Carnap and his associates. By his centenary, however, there emerged a new and fuller understanding of his ideas and of their importance for twentieth-century philosophy.

RICHARD CREATH

CARNEADES (214–129 BC)

The Greek philosopher Carneades was head of the Academy from 167 to 137 BC. Born in North Africa he migrated to Athens, where he studied logic with the Stoic Diogenes of Babylon; but he was soon seduced by the Academy, to which his allegiance was thereafter lifelong. He was a celebrated figure; and in 155 BC he was sent by Athens to Rome as a political ambassador, where he astounded the youth by his rhetorical powers and outraged their elders by his arguments against justice.

Under Carneades' direction the Academy remained sceptical. But he enlarged the sceptical armoury – in particular, he deployed sorites arguments against various dogmatic positions. He also broadened the target of sceptical attack: thus he showed an especial interest in ethics, where his 'division' of possible ethical theories served later as a standard framework for thought on the subject. But his major innovation concerned the notion of 'the plausible' (*to pithanon*). Even if we cannot determine which appearances are true and which false, we are able to distinguish the plausible from the implausible – and further to distinguish among several grades of plausibility. It is disputed – and it was disputed among his immediate followers – how, if at all, Carneades' remarks on the plausible are to be reconciled with his scepticism.

CASSIRER, ERNST (1874–1945)

Cassirer is one of the major figures in the development of philosophical idealism in the first half of the twentieth century. He is known for his

philosophy of culture based on his conception of 'symbolic form', for his historical studies of the problem of knowledge in the rise of modern philosophy and science and for his works on the Renaissance and the Enlightenment. Cassirer expanded Kant's critique of reason to a critique of culture by regarding the symbol as the common denominator of all forms of human thought, imagination and experience. He delineates symbolic forms of myth, religion, language, art, history and science and defines the human being as the 'symbolizing animal'. All human experience occurs through systems of symbols. Language is only one such system; the images of myth, religion and art and the mathematical structures of science are others.

Being of Jewish faith, Cassirer left Germany in 1933 with the rise of Nazism, going first to Oxford, then to university positions in Sweden and the USA. In the last period of his career he applied his philosophy of culture generally and his conception of myth specifically to a critique of political myths and to the study of irrational forces in the state.

CATEGORICAL IMPERATIVE

See Kantian ethics

CATEGORIES

Categories are hard to describe, and even harder to define. This is in part a consequence of their complicated history, and in part because category theory must grapple with vexed questions concerning the relation between linguistic or conceptual categories on the one hand, and objective reality on the other. In the mid-fourth century BC, Aristotle initiates discussion of categories as a central enterprise of philosophy. In the *Categories* he presents an 'ontological' scheme which classifies all being into ten ultimate types, but in the *Topics* introduces the categories as different kinds of predication, that is, of items such as 'goodness' or 'length of a tennis court' or 'red', which can be 'predicated of' subjects. He nowhere attempts either to justify what he includes in his list of categories or to establish its completeness, and relies throughout on the unargued conviction that language faithfully represents the most basic features of reality. In the twentieth century, a test for category membership was recommended by Ryle, that of absurdity: concepts or expressions differ in logical type when their combination produces sentences which are palpable nonsense. Kant, working in the eighteenth century, derives his categories from a consideration of aspects of judgments, hoping in this manner to ensure that his scheme will consist exclusively of a priori concepts which might constitute an objective world. The Sinologist Graham argues that the categories familiar in the West mirror Indo-European linguistic structure, and that an experimental Chinese scheme exhibits suggestively different properties, but his relativism is highly contentious.

CATHARSIS

See Emotion in response to art; Katharsis; Tragedy

CAUSATION

Two opposed viewpoints raise complementary problems about causation. The first is from Hume: watch the child kick the ball. You see the foot touch the ball and the ball move off. But do you see the foot *cause* the ball to move? And if you do not see it, how do you know that that is what happened? Indeed if all our experience is like this, and all of our ideas come from experience, where could we get the idea of causation in the first place?

The second is from Kant. We can have no ideas at all with which to experience nature – we cannot experience the child as a child nor the motion as a motion – unless we have organized the experience into a causal order in which one thing necessarily gives rise to another. The problem for the Kantian viewpoint is to explain how, in advance of experiencing nature in various specific ways, we are able to provide such a complex organization for our experience.

For the Kantian the objectivity of causality is a presupposition of our experience of events external to ourselves. The Humean viewpoint must find something in our experience that provides sufficient ground for causal claims. Regular associations between putative causes and effects are the proposed solution. This attention to regular associations connects the Humean tradition with modern statistical techniques used in the social sciences to establish causal laws.

Modern discussions focus on three levels of causal discourse. The first is about singular causation: about individual 'causings' that occur at specific times and places, for example, 'the cat lapped up the milk'. The second is about causal laws: laws about what features reliably cause or prevent other features, as in, 'rising inflation

prevents unemployment'. The third is about causal powers. These are supposed to determine what kinds of singular causings a feature can produce or what kinds of causal laws can be true of it – 'aspirins have the power to relieve headaches' for example.

Contemporary anglophone work on causality has centred on two questions. First, 'what are the relations among these levels?' The second is from reductive empiricisms of various kinds that try to bar causality from the world, or at least from any aspects of the world that we can find intelligible: 'What is the relation between causality (on any one of the levels) and those features of the world that are supposed to be less problematic?' These latter are taken by different authors to include different things. Sensible or measurable properties like 'redness' or 'electric voltage' have been attributed a legitimacy not available to causal relations like 'lapping-up' or 'pushing over': sometimes it is 'the basic properties studied by physics'. So-called 'occurrent' properties have also been privileged over dispositional properties (like water-solubility) and powers. At the middle level where laws of nature are concerned, laws about regular associations between admissible features – whether these associations are deterministic or probabilistic – have been taken as superior to laws about what kinds of effects given features produce.

NANCY CARTWRIGHT

CAUSATION IN THE LAW

Causal language is pervasive in the law, especially in those areas, such as contract law, tort law and criminal law, that deal with legal responsibility for the adverse consequences of voluntary and involuntary human interactions. Yet there are widely varying theories on the nature and role of causation in the law. At one extreme, the causal minimalists claim that causation plays little or no role in attributions of legal responsibility. At the opposite extreme, the causal maximalists claim that causation is the primary or sole determinant of legal responsibility. These divergent views are rooted in different conceptions of: (1) the nature or meaning of causation, (2) the relationship between causation and attributions of legal responsibility, and (3) the basic purposes of the relevant areas of law.

Much of the disagreement and confusion stems from the ambiguous usages of causal language in the law, which follow the ambiguous usages of causal language in ordinary, non-legal discourse. In both areas, causal language is sometimes used in its primary sense to refer to the content and operation of the empirical laws of nature, but at other times it is used in a more restricted normative sense to signify that one of the contributing conditions has been identified as being more important than the other conditions, in relation to some particular purpose. The relevant purpose in the law is the attribution of legal responsibility for some consequence. Thus, in legal discourse, causal language is ambiguously employed to grapple not only with the empirical issue of causal contribution but also with the normative issue of legal responsibility. The failure to use language that clearly identifies and distinguishes these two issues has generated considerable disagreement and confusion over each issue and the nature of the relationship between them.

Further disagreement and confusion have been generated by the difficulty of providing useful, comprehensive criteria for the resolution of each of these issues. The most widely used criterion for the empirical issue of causal contribution is the necessary-condition (*conditio sine qua non*) test. This test has been subjected to considerable criticism as being over-inclusive or under-inclusive or both, and as inviting or even requiring resort to normative policy issues to resolve what supposedly is a purely empirical issue. The deficiencies of the necessary-condition test, coupled with the difficulties encountered in trying to devise a useful alternative test that does not beg the question, have led many to conclude that there is no purely empirical concept of causation, and that there is thus no more than a minimal role for causation in the attribution of legal responsibility.

This causal-minimalist position has been especially attractive to the legal economists and the critical legal scholars, since it undermines the traditional conception of the law as an instrument of interactive justice, whereby everyone is required to avoid causing injury to the persons and property of others through interactions that fail to respect properly those others' equal dignity and autonomy. The traditional conception, with its focus on individual autonomy, rights and causation, is inconsistent with the social-welfare maximizing theories of the legal economists and the anti-liberal, deconstructionist programme of the critical legal scholars. The members of each causal-minimalist group therefore argue that the concept of causation should be: (a) jettisoned entirely and replaced by direct resort to the social policy goals which they believe do or should determine the ultimate incidence and extent of legal responsibility; (b) redefined as being reducible to those social policy goals; or (c) retained as useful rhetoric that can be manipulated to achieve or camouflage the pursuit of those social policy goals.

RICHARD W. WRIGHT

CAUSATION, INDIAN THEORIES OF

Causation was acknowledged as one of the central problems in Indian philosophy. The classical Indian philosophers' concern with the problem basically arose from two sources: first, the cosmogonic speculations of the Vedas and the Upaniṣads, with their search for some simple unitary cause for the origin of this complex universe; and second, the Vedic concern with ritual action (*karman*) and the causal mechanisms by which such actions bring about their unseen, but purportedly cosmic, effects. Once the goal of liberation (*mokṣa*) came to be accepted as the highest value, these two strands of thought entwined to generate intense interest in the notion of causation. The systematic philosophers of the classical and medieval periods criticized and defended competing theories of causation. These theories were motivated partly by a desire to guarantee the efficacy of action and hence the possibility of attaining liberation, partly by a desire to understand the nature of the world and hence how to negotiate our way in it so as to attain liberation.

Indian philosophers extensively discussed a number of issues relating to causation, including the nature of the causal relation, the definitions of cause and effect, and classifications of kinds of causes. Typically they stressed the importance of the material cause, rather than (as in Western philosophy) the efficient cause. In India only the Cārvāka materialists denied causation or took it to be subjective. This is unsurprising given that a concern with demonstrating the possibility of liberation motivated the theories of causation, for only the Cārvākas denied this possibility. The orthodox Hindu philosophers and the heterodox Buddhists and Jainas all accepted both the possibility of liberation and the reality of causation, though they differed sharply (and polemically) about the details.

The Indian theories of causation are traditionally classified by reference to the question of whether the effect is a mode of the cause. According to this taxonomy there are two principal theories of causation. One is the identity theory (*satkāryavāda*), which holds that the effect is identical with the cause, a manifestation of what is potential in the cause. This is the Sāṅkhya-Yoga view, though that school's particular version of it is sometimes called transformation theory (*pariṇāmavāda*). Advaita Vedānta holds an appearance theory (*vivartavāda*), which is often considered a variant of the identity theory. According to the appearance theory effects are mere appearances of the underlying reality, Brahman. Since only Brahman truly exists, this theory is also sometimes called *satkāraṇavāda* (the theory that the cause is real but the effect is not).

The other principal theory of causation is the nonidentity theory (*asatkāryavāda*), which denies that the effect pre-exists in its cause and claims instead that the effect is an altogether new entity. Both adherents of Nyāya-Vaiśeṣika and the Buddhists are usually classified as nonidentity theorists, but they differ on many important details. One of these is whether the cause continues to exist after the appearance of the effect: Nyāya-Vaiśeṣika claims it does, the Buddhists mostly claim it does not.

Finally, some philosophers try to take the middle ground and claim that an effect is both identical and nonidentical with its cause. This is the position of the Jainas and of some theistic schools of Vedānta.

CAVELL, STANLEY (1926–)

Born in Atlanta, Georgia, Stanley Cavell has held the Walter M. Cabot Chair in Aesthetics and the General Theory of Value at Harvard University since 1963. The range, diversity and distinctiveness of his writings are unparalleled in twentieth-century Anglo-American philosophy. As well as publishing essays on modernist painting and music, he has created a substantial body of work in film studies, literary theory and literary criticism; he has introduced new and fruitful ways of thinking about psychoanalysis and its relationship with philosophy; and his work on Heidegger and Derrida, taken together with his attempts to revitalize the tradition of Emersonian Transcendentalism, have defined new possibilities for a distinctively American contribution to philosophical culture. This complex oeuvre is unified by a set of thematic concerns – relating to scepticism and moral perfectionism – which are rooted in Cavell's commitment to the tradition of ordinary language philosophy, as represented in the work of J.L. Austin and Wittgenstein.

STEPHEN MULHALL

CAVENDISH, MARGARET LUCAS (1623–73)

The only seventeenth-century woman to publish numerous books on natural philosophy, Cavendish presented her materialism in a wide range of literary forms. She abandoned her early commitment to Epicurean atomism and, rejecting the mechanical model of natural change, embraced an organicist materialism. She also addressed the relations that hold among philosophy, gender and literary genre.

CHANGE

Change in general may be defined as the variation of properties (whether of things or of regions of space) over time. But this definition is incomplete in a number of respects. The reference to properties and time raises two important questions. The first concerns whether we need to specify further the kinds of properties which are involved in change. If we define change in an object as temporal variation of its properties we are faced with the problem that some properties of an object may alter without there being a consequent change in the object itself. The second question concerns the passage of time: does temporal variation constitute change only in virtue of some feature of time itself, namely the fact (or putative fact) that time passes? Some philosophers have wished to reject the notion of time's passage. Are they thereby committed to a picture of the world as unchanging?

ROBIN LE POIDEVIN

CHAOS THEORY

Chaos theory is the name given to the scientific investigation of mathematically simple systems that exhibit complex and unpredictable behaviour. Since the 1970s these systems have been used to model experimental situations ranging from the early stages of fluid turbulence to the fluctuations of brain wave activity. This complex behaviour does not arise as a result of the interaction of numerous sub-systems or from intrinsically probabilistic equations. Instead, chaotic behaviour involves the rapid growth of any inaccuracy. The slightest vagueness in specifying the initial state of such a system makes long-term predictions impossible, yielding behaviour that is effectively random. The existence of such behaviour raises questions about the extent to which predictability and determinism apply in the physical world. Chaos theory addresses the questions of how such behaviour arises and how it changes as the system is modified. Its new analytical techniques invite a reconsideration of scientific methodology.

STEPHEN H. KELLERT

CHARITY, PRINCIPLE OF

The principle of charity governs the interpretation of the beliefs and utterances of others. It urges charitable interpretation, meaning interpretation that maximizes the truth or rationality of what others think and say. Some formulations of the principle concern primarily rationality, recommending attributions of rational belief or assertion. Others concern primarily truth, recommending attributions of true belief or assertion. Versions of the principle differ in strength. The weakest urge charity as one consideration among many. The strongest hold that interpretation is impossible without the assumption of rationality or truth.

The principle has been put to various philosophical uses. Students are typically instructed to follow the principle when interpreting passages and formulating the arguments they contain. The principle also plays a role in philosophy of mind and language and in epistemology. Philosophers have argued that the principle of charity plays an essential role in characterizing the nature of belief and intentionality, with some philosophers contending that beliefs must be mostly true. A version of the principle has even served as a key premise in a widely discussed argument against epistemological scepticism.

RICHARD FELDMAN

CHINESE PHILOSOPHY

Any attempt to survey an intellectual tradition which encompasses more than four thousand years would be a daunting task even if it could be presumed that the reader shares, at least tacitly, many of the assumptions underlying that tradition. However, no such commonalities can be assumed in attempting to introduce Asian thinking to Western readers. Until the first Jesuit incursions in the late sixteenth century, China had developed in virtual independence of the Indo-European cultural experience and China and the Western world remained in almost complete ignorance of one another.

The dramatic contrast between Chinese and Western modes of philosophic thinking may be illustrated by the fact that the tendency of European philosophers to seek out the being of things, the essential reality lying behind appearances, would meet with little sympathy among Chinese thinkers, whose principal interests lie in the establishment and cultivation of harmonious relationships within their social ambiance. Contrasted with Anglo-European philosophic traditions, the thinking of the Chinese is far more concrete, this-worldly and, above all, practical.

One reason for this difference is suggested by the fact that cosmogonic and cosmological myths played such a minor role in the development of Chinese intellectual culture and that, as a consequence, Chinese eyes were focused not upon issues of cosmic order but upon more mundane questions of how to achieve communal harmony within a relatively small social nexus. The rather profound linguistic and ethnic localism of what Pliny the Elder described as a 'stay-at-home' China, reinforced by a relative freedom from intercultural contact, generated traditional radial communities in which moral, aesthetic and spiritual values could remain relatively implicit and unarticulated. By contrast, in the West these norms had to be abstracted and raised to the level of consciousness to adjudicate conflicts occasioned by the complex ethnic and linguistic interactions associated with the development of a civilization rooted almost from the beginning in the confluence of Greek, Hebrew, and Latin civilizations.

The distinctive origins and histories of Chinese and Western civilizations are manifested in a number of important ways. The priority of logical reasoning in the West is paralleled in China by the prominence of less formal uses of analogical, parabolic and literary discourse. The Chinese are largely indifferent to abstract analyses that seek to maintain an objective perspective, and are decidedly anthropocentric in their motivations for the acquisition, organization and transmission of knowledge. The disinterest in dispassionate speculations upon the nature of things, and a passionate commitment to the goal of social harmony was dominant throughout most of Chinese history. Indeed, the interest in logical speculations on the part of groups such as the sophists and the later Mohists was short-lived in classical China.

The concrete, practical orientation of the Chinese toward the aim of communal harmony conditioned their approach toward philosophical differences. Ideological conflicts were seen, not only by the politicians but by the intellectuals themselves, to threaten societal wellbeing. Harmonious interaction was finally more important to these thinkers than abstract issues of who had arrived at the 'truth'. Perhaps the most obvious illustration of the way the Chinese handled their theoretical conflicts is to be found in mutual accommodation of the three emergent traditions of Chinese culture, Confucianism, Daoism and Buddhism. Beginning in the Han dynasty (206 BC–AD 220), the diverse themes inherited from the competing 'hundred schools' of pre-imperial China were harmonized within Confucianism as it ascended to become the state ideology. From the Han synthesis until approximately the tenth century AD, strong Buddhist and religious Daoist influences continued to compete with persistent Confucian themes, while from the eleventh century to the modern period, Neoconfucianism – a Chinese neoclassicism – absorbed into itself these existing tensions and those that would emerge as China, like it or not, confronted Western civilization.

In the development of modern China, when Western influence at last seemed a permanent part of Chinese culture, the values of traditional China have remained dominant. For a brief period, intellectual activity surrounding the May Fourth movement in 1919 seemed to be leading the Chinese into directions of Western philosophic interest. Visits by Bertrand Russell and John Dewey, coupled with a large number of Chinese students seeking education in Europe, Great Britain and the USA, promised a new epoch in China's relations with the rest of the world. However, the Marxism that Mao Zedong sponsored in China was 'a Western heresy with which to confront the West'. Mao's Marxism quickly took on a typically 'Chinese' flavour, and China's isolation from Western intellectual currents continued essentially unabated.

CHINESE ROOM ARGUMENT

John Searle's 'Chinese room' argument aims to refute 'strong AI' (artificial intelligence), the view that instantiating a computer program is sufficient for having contentful mental states. Imagine a program that produces conversationally appropriate Chinese responses to Chinese utterances. Suppose Searle, who understands no Chinese, sits in a room and is passed slips of paper bearing strings of shapes which, unbeknown to him, are Chinese sentences. Searle performs the formal manipulations of the program and passes back slips bearing conversationally appropriate Chinese responses. Searle seems to instantiate the program, but understands no Chinese. So, Searle concludes, strong AI is false.

ROBERT VAN GULICK

CHISHOLM, RODERICK MILTON (1916–99)

Chisholm was an important analytic philosopher of the second half of the twentieth century. His work in epistemology, metaphysics and ethics is

characterized by scrupulous attention to detail, the use of a few basic, undefined or primitive terms, and extraordinary clarity. One of the first Anglo-American philosophers to make fruitful use of Brentano and Meinong, Chisholm translated many of Brentano's philosophical writings. As one of the great teachers, Chisholm is widely known for the three editions of *Theory of Knowledge*, a short book and the standard text in US graduate epistemology courses. An ontological Platonist, Chisholm defends human free will and a strict sense of personal identity.

DAVID BENFIELD

CHOMSKY, NOAM (1928–)

Fish swim, birds fly, people talk. The talents displayed by fish and birds rest on specific biological structures whose intricate detail is attributable to genetic endowment. Human linguistic capacity similarly rests on dedicated mental structures many of whose specific details are an innate biological endowment of the species. One of Chomsky's central concerns has been to press this analogy and uncover its implications for theories of mind, meaning and knowledge.

This work has proceeded along two broad fronts.

First, Chomsky has fundamentally restructured grammatical research. Due to his work, the central object of study in linguistics is 'the language faculty', a postulated mental organ which is dedicated to acquiring linguistic knowledge and is involved in various aspects of language-use, including the production and understanding of utterances. The aim of linguistic theory is to describe the initial state of this faculty and how it changes with exposure to linguistic data. Chomsky characterizes the initial state of the language faculty as a set of principles and parameters. Language acquisition consists in setting these open parameter values on the basis of linguistic data available to a child. The initial state of the system is a Universal Grammar (UG): a super-recipe for concocting language-specific grammars. Grammars constitute the knowledge of particular languages that result when parametric values are fixed.

Linguistic theory, given these views, has a double mission. First, it aims to 'adequately' characterize the grammars (and hence the mental states) attained by native speakers. Theories are 'descriptively adequate' if they attain this goal. In addition, linguistic theory aims to explain how grammatical competence is attained. Theories are 'explanatorily adequate' if they show how descriptively adequate grammars can arise on the basis of exposure to 'primary linguistic data' (PLD): the data children are exposed to and use in attaining their native grammars. Explanatory adequacy rests on an articulated theory of UG, and in particular a detailed theory of the general principles and open parameters that characterize the initial state of the language faculty (that is, the biologically endowed mental structures).

Chomsky has also pursued a second set of concerns. He has vigorously criticized many philosophical nostrums from the perspective of this revitalized approach to linguistics. Three topics he has consistently returned to are:

- Knowledge of language and its general epistemological implications
- Indeterminacy and underdetermination in linguistic theory
- Person-specific 'I-languages' versus socially constituted 'E-languages' as the proper objects of scientific study.

CHRISTINE DE PIZAN (1365–*c.*1430)

Christine de Pizan, France's 'first woman of letters', is primarily remembered as a courtly poet and a propagandist for women. Her extensive writings were influenced by the early humanists, reflecting an interest in education (particularly for women and young people) and in government. Following Aquinas, Christine defined wisdom as the highest intellectual virtue and tried to apply the concept of the just war to contemporary problems. Her works are also noteworthy for their contribution to the transmission of Italian literature to Parisian intellectual circles.

CHARITY CANNON WILLARD

CHURCH'S THEOREM AND THE DECISION PROBLEM

Church's theorem, published in 1936, states that the set of valid formulas of first-order logic is not effectively decidable: there is no method or algorithm for deciding which formulas of first-order logic are valid. Church's paper exhibited an undecidable combinatorial problem $\mathcal{P}$ and showed that $\mathcal{P}$ was representable in first-order logic. If first-order logic were decidable, $\mathcal{P}$ would also be decidable. Since $\mathcal{P}$ is undecidable, first-order logic must also be undecidable.

Church's theorem is a negative solution to the decision problem (*Entscheidungsproblem*), the problem of finding a method for deciding whether a given formula of first-order logic is valid, or satisfiable, or neither. The great contribution of Church (and, independently, Turing) was not merely to prove that there is no method but also to propose a mathematical definition of the notion of 'effectively solvable problem', that is, a problem solvable by means of a method or algorithm.

ROHIT PARIKH

CHURCH'S THESIS

An algorithm or mechanical procedure A is said to 'compute' a function f if, for any *n* in the domain of f, when given *n* as input, A eventually produces f*n* as output. A function is 'computable' if there is an algorithm that computes it. A set *S* is 'decidable' if there is an algorithm that decides membership in *S*: if, given any appropriate *n* as input, the algorithm would output 'yes' if $n \in S$, and 'no' if $n \notin S$. The notions of 'algorithm', 'computable' and 'decidable' are informal (or pre-formal) in that they have meaning independently of, and prior to, attempts at rigorous formulation.

Church's thesis, first proposed by Alonzo Church in a paper published in 1936, is the assertion that a function is computable if and only if it is recursive: 'We now define the notion . . . of an effectively calculable function . . . by identifying it with the notion of a recursive function . . . .' Independently, Alan Turing argued that a function is computable if and only if there is a Turing machine that computes it; and he showed that a function is Turing-computable if and only if it is recursive.

Church's thesis is widely accepted today. Since an algorithm can be 'read off' a recursive derivation, every recursive function is computable. Three types of 'evidence' have been cited for the converse. First, every algorithm that has been examined has been shown to compute a recursive function. Second, Turing, Church and others provided analyses of the moves available to a person following a mechanical procedure, arguing that everything can be simulated by a Turing machine, a recursive derivation, and so on. The third consideration is 'confluence'. Several different characterizations, developed more or less independently, have been shown to be coextensive, suggesting that all of them are on target. The list includes recursiveness, Turing computability, Herbrand–Gödel derivability, λ-definability and Markov algorithm computability.

STEWART SHAPIRO

CICERO, MARCUS TULLIUS (106–43 BC)

Cicero, pre-eminent Roman statesman and orator of the first century BC and a prolific writer, composed the first substantial body of philosophical work in Latin. Rising from small-town obscurity to the pinnacle of Rome's staunchly conservative aristocracy, he devoted most of his life to public affairs. But he was deeply interested in philosophy throughout his life, and during two intervals of forced withdrawal from politics wrote two series of dialogues, first elaborating his political ideals and later examining central issues in epistemology, ethics and theology. Designed to establish philosophical study as an integral part of Roman culture, these works are heavily indebted to Greek philosophy, and some of the later dialogues are largely summaries of Hellenistic debates. But Cicero reworked his sources substantially, and his methodical expositions are thoughtful, judicious and, on questions of politics and morals, often creative. An adherent of the sceptical New Academy, he was opposed to dogmatism but ready to accept the most cogent arguments on topics important to him. His vigorously argued and eloquent critical discussions of perennial problems greatly enriched the intellectual and moral heritage of Rome and shaped Western traditions of liberal education, republican government and rationalism in religion and ethics. These works also afford invaluable insight into the course of philosophy during the three centuries after Aristotle.

CITIZENSHIP

Within political philosophy, citizenship refers not only to a legal status, but also to a normative ideal – the governed should be full and equal participants in the political process. As such, it is a distinctively democratic ideal. People who are governed by

monarchs or military dictators are subjects, not citizens. Most philosophers therefore view citizenship theory as an extension of democratic theory. Democratic theory focuses on political institutions and procedures; citizenship theory focuses on the attributes of individual participants.

One important topic in citizenship theory concerns the need for citizens to actively participate in political life. In most countries participation in politics is not obligatory, and people are free to place private commitments ahead of political involvement. Yet if too many citizens are apathetic, democratic institutions will collapse. Another topic concerns the identity of citizens. Citizenship is intended to provide a common status and identity which helps integrate members of society. However, some theorists question whether common citizenship can accommodate the increasing social and cultural pluralism of modern societies.

WILL KYMLICKA

CIVIL DISOBEDIENCE

According to common definitions, civil disobedience involves a public and nonviolent breach of law that is committed in order to change a law or policy, and in order to better society. More, those classed as civilly disobedient must be willing to accept punishment. Why is the categorization of what counts as civil disobedience of practical importance? The usual assumption is that acts of civil disobedience are easier to justify morally than other illegal acts. Acts of civil disobedience, such as those committed by abolitionists, by followers of Mahatma Gandhi and Martin Luther King, Jr and by opponents of the Vietnam War, have been an important form of social protest.

The decision as to what exactly should count as civil disobedience should be guided both by an ordinary understanding of what the term conveys and by what factors are relevant for moral justification. For justification, nonviolence and publicness matter because they reduce the damage of violating the law. Tactics should be proportionate to the evil against which civil disobedience is aimed; someone who assesses the morality of a particular act of civil disobedience should distinguish an evaluation of tactics from an evaluation of objectives.

CLARKE, SAMUEL (1675–1729)

Regarded in his lifetime along with Locke as the leading English philosopher, Clarke was best known in his role as an advocate of a thoroughgoing natural theology and as a defender of Newtonianism, most notably in his famous correspondence with Leibniz. His natural theology was set out in his Boyle lectures of 1704 and 1705, but it left little room for revelation, and endeared him to neither side in the quarrel between deists and orthodox Anglicans. A staunch proponent of Newtonian natural philosophy, he defended it against criticisms of its notions of gravity and absolute space.

CLONING

'Cloning' is the popular name given to Cell Nuclear Replacement (CNR) or Cell Nuclear Transfer (CNT) techniques. CNR involves a recipient cell, generally an egg (oocyte), and a donor cell. The nucleus of the donor cell is introduced into the oocyte. With appropriate stimulation the oocyte is induced to develop. In some cases, the created embryo may be implanted into a viable womb and developed to term. The first mammal to be born by CNR was Dolly the sheep (1996–2003).

It is thought that CNR may have various potential applications ranging from reproduction to treatment of some of the most serious and life-threatening diseases that afflict humankind (such as cancer, Alzheimer's, Parkinson's disease, spinal cord injuries). However, many technical problems must be addressed and resolved before CNR becomes viable for use in either therapy or reproduction. Although research on CNR is still in its early stages, CNR (cloning) attracts people's attention in a way that do few other advances in biomedical research. Public debate on cloning has unfortunately been influenced more by fiction than science. The horrendous or absurd scenarios pictured in novels and films are often mistakenly believed to be possible, or even likely, outcomes of cloning. The international community, immediately after news of the birth of Dolly, imposed restrictions that may make it difficult to refine the technique used. Against 'reproductive cloning' a prohibition is enforced virtually everywhere. 'Reproductive cloning' is considered offensive to human dignity and a threat to the well-being of the child or even to the future of humankind. Most of these objections are based on either a misunderstanding of CNR or on inconsistent philosophical arguments. Against

'therapeutic cloning' objections are also raised. The strongest are that CNR involves the creation and destruction of embryos, and this is widely believed to be unethical. Advocates of this position contend that, although CNR may save human lives, the technique still involves the taking of an innocent life and therefore is the equivalent of killing one person to save another. The debate on the moral status of the embryo is ongoing, in bioethics, philosophy and theology. However, if the arguments against the killing of the embryo for the morally important, life-saving purposes envisaged for CNR were to be accepted, then the current legal and social context of most European countries would have to be revised, and abortion and in vitro fertilization (IVF) made criminal offences. Abortion and IVF (which involves creation of extra-embryos that may be destroyed) are in fact accepted practices in most European countries. Those who believe that abortion, even in its therapeutic form, and IVF are acceptable, admit that it may be ethical to destroy an embryo either to save a life or to treat infertility. If this is accepted, it is unclear why is it unacceptable that embryos are used to treat highly serious and lethal diseases (cancer or Parkinson's disease for example).

COERCION

Coercion (also called 'duress') is one of the basic exculpating excuses both in morality and in some systems of criminal law. Unlike various kinds of direct compulsion that give a victim no choice, a coercee is left with a choice, albeit a very unappealing one. They can do what is demanded, or can refuse, opting instead for the consequences, with which they are threatened. Sometimes courts find that the coercive threat that led the defendant to act as they did was objectively resistible by any person of reasonable fortitude, especially when the defendant's conduct was gravely harmful to others or to the state.

A proposal is an offer when it projects for the recipient's consideration a prospect that is welcome in itself, and not harmful or unwelcome beyond what would happen in the normal course of events. Coercive offers, according to some writers, are those that force a specific choice from the victim while actually enhancing their freedom. Some argue, however, that genuine coercion requires the active and deliberate creation of a vulnerability, and not mere opportunistic exploitation of a vulnerability discovered fortuitously.

JOEL FEINBERG

COHEN, HERMANN (1842–1918)

Hermann Cohen was the founder of the Marburg School of Neo-Kantianism and a major influence on twentieth-century Jewish thought. *Die Religion der Vernunft aus den Quellen des Judentums* (Religion of Reason out of the Sources of Judaism) (1919) is widely credited with the renewal of Jewish religious philosophy. Cohen's philosophy of Judaism is inextricably linked with his general philosophical position. But his system of critical idealism in logic, ethics, aesthetics and psychology did not originally include a philosophy of religion. The mainly Protestant Marburg School in fact regarded Cohen's Jewish philosophy as an insufficient solution to the philosophical problem of human existence and to that of determining the role of religion in human culture. Thinkers who favoured a new, more existentialist approach in Jewish thought, however, saw Cohen's introduction of religion into the system as a daring departure from the confines of philosophical idealism.

Cohen identified the central Jewish contribution to human culture as the development of a religion that unites historical particularity with ethical universality. At the core of this religion of reason is the interdependence of the idea of God and that of the human being. Cohen derives this theme from the Jewish canon through a philosophical analysis based on his transcendental idealism.

COLLINGWOOD, ROBIN GEORGE (1889–1943)

Collingwood was the greatest British philosopher of history of the twentieth century. His experience as a practising historian of Roman Britain led him to believe that the besetting vice of philosophy is to abstract propositions away from the context of the practical problems and questions that gave rise to them. Until we know the practical context of problems and questions to which a proposition is supposed to be an answer, we do not know what it means. In this respect his concern with the living activities of language users parallels that of the later Wittgenstein. Collingwood also believed that the interpretation of others was not a scientific exercise of fitting their behaviour into a network of generalizations, but a matter of rethinking their thoughts for oneself. His conviction that this ability, which he identified with historical thinking, was the neglected and crucial component of all human thought stamped him as original, or even a maverick, during his own lifetime. He also shared with Wittgenstein the belief that quite apart from containing propositions that can be evaluated as true or false, systems of thought depend upon 'absolute presuppositions', or a framework or scaffolding of ideas that may change with time. The business of metaphysics is to reconstruct the framework that operated at particular periods of history. Collingwood had extensive moral and political interests, and his writings on art, religion and science confirm his stature as one of the greatest polymaths of twentieth-century British philosophy.

SIMON BLACKBURN

COLOUR AND QUALIA

There are two basic philosophical problems about colour. The first concerns the nature of colour itself. That is, what sort of property is it? When I say of the shirt that I am wearing that it is red, what sort of fact about the shirt am I describing? The second problem concerns the nature of colour experience. When I look at the red shirt I have a visual experience with a certain qualitative character – a 'reddish' one. Thus colour seems in some sense to be a property of my sensory experience, as well as a property of my shirt. What sort of mental property is it?

Obviously, the two problems are intimately related. In particular, there is a great deal of controversy over the following question: if we call the first sort of property 'objective colour' and the second 'subjective colour', which of the two, objective or subjective colour, is basic? Or do they both have an independent ontological status?

Most philosophers adhere to the doctrine of physicalism, the view that all objects and events are ultimately constituted by the fundamental physical particles, properties and relations described in physical theory. The phenomena of both objective and subjective colour present problems for physicalism. With respect to objective colour, it is difficult to find any natural physical candidate with which to identify it. Our visual system responds in a similar manner to surfaces that vary along a wide range of physical parameters, even with respect to the reflection of light waves. Yet what could be more obvious than the fact that objects are coloured?

In the case of subjective colour, the principal topic of this entry, there is an even deeper puzzle. It is natural to think of the reddishness of a visual experience – its qualitative character – as an intrinsic property of the experience. Intrinsic properties are distinguished from relational properties in that an object's possession of the former does not depend on its relation to other objects, whereas its possession of the latter does. If subjective colour is intrinsic, then it would seem to be a neural property of a brain state. But what sort of neural property could explain the reddishness of an experience? Furthermore, reduction of subjective colour to a neural property would rule out even the possibility that forms of life with different physiological structures, or intelligent robots, could have experiences of the same qualitative type as our experiences of red. While some philosophers endorse this consequence, many find it quite implausible.

Neural properties seem best suited to explain how certain functions are carried out, and therefore it might seem better to identify subjective colour with the property of playing a certain functional role within the entire cognitive system realized by the brain. This allows the possibility that structures physically different from human brains could support colour experiences of the same type as our own. However, various puzzles undermine the plausibility of this claim. For instance, it seems possible that two people could agree in all their judgments of relative similarity and yet one sees green where the other sees red. If this 'inverted spectrum' case is a genuine logical possibility, as many philosophers advocate, then it appears that subjective colour must not be a matter of functional role, but rather an intrinsic property of experience.

Faced with the dilemmas posed by subjective colour for physicalist doctrine, some philosophers opt for eliminativism, the doctrine that subjective colour is not a genuine, or real, phenomenon after

all. On this view the source of the puzzle is a conceptual confusion; a tendency to extend our judgments concerning objective colour, what appear to be intrinsic properties of the surfaces of physical objects, onto the properties of our mental states. Once we see that all that is happening 'inside' is a perceptual judgment concerning the properties of external objects, we will understand why we cannot locate any state or property of the brain with which to identify subjective colour.

The controversy over the nature of subjective colour is part of a wider debate about the subjective aspect of conscious experience more generally. How does the qualitative character of experience – what it is like to see, hear and smell – fit into a physicalist scientific framework? At present all of the options just presented have their adherents, and no general consensus exists.

JOSEPH LEVINE

COLOUR, THEORIES OF

The world as perceived by human beings is full of colour. The world as described by physical scientists is composed of colourless particles and fields. Philosophical theories of colour since the Scientific Revolution have been driven primarily by a desire to harmonize these two apparently conflicting pictures of the world. Any adequate theory of colour has to be consistent with the characteristics of colour as perceived without contradicting the deliverances of the physical sciences.

Given this conception of the aim of a theory of colour, there are three possibilities for resolving the apparent conflict between the scientific and perceptual facts. The first is to deny that physical objects have colours. Theories of this kind admit that objects appear coloured but maintain that these appearances are misleading. The conflict is resolved by removing colour from the external world. Second, it might be that colour is a relational property. For an object to possess a particular colour it must be related in the right way to a perceiver. One common version of this view analyses colour as a disposition to cause particular kinds of perceptual experience in a human being. Since the physical sciences deal only with the intrinsic properties of physical objects and their relations to other physical objects and not their relations to perceiving subjects, the possibility of conflict is removed. A third possible response is to maintain that colour really is a property of external objects and that the conflict is merely apparent. Some theories of this form maintain that colour is identical to a physical property of objects. Others maintain that colour is a property that physical objects possess over and above all their physical properties. Philosophical discussions of colour typically take the form of either elaborating on one of these three possibilities or attempting to show more generally that one of these three types of response is to be preferred to the others.

DAVID R. HILBERT

COMEDY

In the narrowest sense, comedy is drama that makes us laugh and has a happy ending. In a wider sense it is also humorous narrative literature with a happy ending. In the widest sense, comedy includes any literary or graphic work, performance or other art intended to amuse us.

Comedy began at about the same time as tragedy, and because they represent alternative attitudes toward basic issues in life, it is useful to consider them together. Unfortunately, several traditional prejudices discriminate against comedy and in favour of tragedy. There are four standard charges against comedy: it emphasizes the animal aspects of human life, encourages disrespect for leaders and institutions, is based on malice, and endangers our morality. These charges are easily answered, for none picks out something that is both essential to comedy and inherently vicious. In fact, once we get past traditional prejudices, several of the differences between comedy and tragedy can be seen as advantages. While tragedy tends to be idealistic and elitist, for example, comedy tends to be pragmatic and egalitarian. While tragedy values honour, even above life itself, comedy puts little stock in honour and instead emphasizes survival. Tragic heroes preserve their dignity but die in the process; comic characters lose their dignity but live to tell the tale. Most generally, comedy celebrates mental flexibility and a realistic acceptance of the limitations of human life. The comic vision of life, in short, embodies a good deal of wisdom.

JOHN MORREALL

COMMON SENSE SCHOOL

The term 'Common Sense School' refers to the works of Thomas Reid and to the tradition of Scottish realist philosophy for which Reid's works were the main source. The ideas of the school were carried abroad – to France; and to the USA, where they were highly influential, particularly among leading academics critical of Calvinism. Interest in Reid and the tradition to which he gave rise was

revived almost a century later by leading American philosophers and their students.
See also: Beattie, J.; Commonsensism; Moore, G.E.

EDWARD H. MADDEN

COMMONSENSISM

'Commonsensism' refers to one of the principal approaches to traditional theory of knowledge where one asks oneself the following Socratic questions: (1) What can I know?; (2) How can I distinguish beliefs that are reasonable for me to have from beliefs that are not reasonable for me to have? and (3) What can I do to replace unreasonable beliefs by reasonable beliefs about the same subject-matter, and to replace beliefs that are less reasonable by beliefs that are more reasonable? The mark of commonsensism is essentially a faith in oneself – a conviction that a human being, by proceeding cautiously, is capable of knowing the world in which it finds itself.

Any inquiry must set out with *some* beliefs. If you had no beliefs at all, you could not even begin to inquire. Hence any set of beliefs is better than none. Moreover, the beliefs that we *do* find ourselves with at any given time have so far survived previous inquiry and experience. And it is psychologically impossible to reject everything that you believe. 'Doubting', Peirce says, 'is not as easy as lying'. Inquiry, guided by common sense, leads us to a set of beliefs which indicates that common sense is on the whole a reliable guide to knowledge. And if inquiry were not thus guided by common sense, how would it be able to answer the three Socratic questions with which it begins?

RODERICK M. CHISHOLM

COMMUNICATION AND INTENTION

The classic attempt to understand communication in terms of the intentions of a person making an utterance was put forward by Paul Grice in 1957. Grice was concerned with actions in which a speaker means something by what they do and what is meant might just as much be false as true. He looked for the essence of such cases in actions intended to effect a change in the recipient. Grice saw successful communication as depending on the recognition by the audience of the speaker's intention. Since then there have been many attempts to refine Grice's work, and to protect it against various problems. There has also been worry that Grice's approach depends on a false priority of psychology over semantics, seeing complex psychological states as existing independently of whether the agent has linguistic means of expressing them.

SIMON BLACKBURN

COMMUNICATIVE RATIONALITY

The concept of 'communicative rationality' is primarily associated with the work of the philosopher and social theorist Jürgen Habermas. According to Habermas, communication through language necessarily involves the raising of 'validity-claims' (distinguished as 'truth', 'rightness' and 'sincerity'), the status of which, when contested, can ultimately only be resolved through discussion. Habermas further contends that speakers of a language possess an implicit knowledge of the conditions under which such discussion would produce an objectively correct result, and these he has spelled out in terms of the features of an egalitarian 'ideal speech situation'. Communicative rationality refers to the capacity to engage in argumentation under conditions approximating to this ideal situation ('discourse', in Habermas' terminology), with the aim of achieving consensus.

Habermas relies on the concept of communicative rationality to argue that democratic forms of social organization express more than simply the preferences of a particular cultural and political tradition. In his view, we cannot even understand a speech-act without taking a stance towards the validity-claim it raises, and this stance in turn anticipates the unconstrained discussion which would resolve the status of the claim. Social and political arrangements which inhibit such discussion can therefore be criticized from a standpoint which does not depend on any specific value-commitments, since for Habermas achieving agreement (*Verständigung*) is a 'telos' or goal which is internal to human language as such. A similar philosophical programme has also been developed by Karl-Otto Apel, who lays more stress on the 'transcendental' features of the argumentation involved.

PETER DEWS

COMMUNISM

Communism is the belief that society should be organized without private property, all productive property being held communally, publicly or in common. A communist system is one based on a community of goods. It is generally presented as a positive alternative to competition, a system that is thought to divide people; communism is expected to draw people together and to create a community. In most cases the arguments for communism

advocate replacing competition with cooperation either for its own sake or to promote a goal such as equality, or to free specific groups of people to serve a higher ideal such as the state or God.

The word *communism* appears to have first been used in the above sense in France in the 1840s to refer to the ideas of thinkers such as Françoise Émile Babeuf (1760–97) and Étienne Cabet (1788–1856), both of whom advocated the collectivization of all productive property. The concept is ancient, however. Early versions of a community of goods exist in myths that describe the earliest stages of human culture; it was a major issue in ancient Athens, a key component of monasticism and became the basis for much criticism of industrial capitalism.

The word communism later became associated with the teachings of Karl Marx (§12) and his followers and came to refer to an authoritarian political system combined with a centralized economic system run by the state. This form of communism has roots in the earlier idea because the ultimate goal of communism, as seen by Marx, was a society in which goods are distributed to people on the basis of need. The older usage continues to exist in a worldwide communal movement and as a standard by which to criticize both capitalism and Marxian communism.

The idea of communism as collectively owned property first appears in the Western tradition in classical Greece. Plato's *Republic* contains a notable early defence (see Plato §14). Prior to the invention of the word, major communist theories can be found in some parts of the Christian Bible, in medieval monasticism and in Thomas More's *Utopia* (1516). In all these cases the basis for collectively owned property is that members of society are freed from the need to devote their time to earning a living or caring for private property so that they can devote themselves to something more important such as the pursuit of knowledge, God or personal fulfilment. The assumption is that the need to provide for oneself or one's family gets in the way of matters considered more important. For example, Plato advocates abolishing the family in his *Republic* because he fears that family ties will both distract the individual from higher things and tempt people to favour one group (family members) over others (non-family members). In monastic communism, which also abolishes the family, all property is owned by the community and each individual member of the community owns nothing, not even their clothes. Everything is provided by the community for each monk or nun; they are, thereby, freed from the burden of property to devote themselves to God. In More's *Utopia* all houses and their furnishings are as near identical as possible and, since location cannot be identical, people move from house to house in regular rotation.

Later, secularized versions of communism stressed the equitable (not necessarily equal) distribution of, or at least access to, resources, but the underlying principle is quite similar. Rather than freeing some or even all people in a society to devote themselves to a higher cause, secular communism is designed to allow everyone to pursue personal fulfilment. It may best be characterized by a slogan adopted by Marx that appears to have been first published on the title page of Cabet's *Voyage en Icarie* (1840): 'From each according to his ability, to each according to his need'. In other words, each person contributes to society to the best of their ability in the areas of work for which they are suited; in return, society provides their basic needs. The underlying assumption is that all human beings deserve to have their needs met simply because they are human beings; differential ability and talent does not make one person more deserving than another. A specific case is the assumption by most communist theorists that there should be no difference in treatment of those who contribute to society through physical labour and those who contribute through mental labour. For example, in 1888 Edward Bellamy published *Looking Backward*, a utopian novel that became an instant bestseller and produced a worldwide movement. In it, Bellamy advocated an absolutely equal income for all members of society that could then be used by each individual to meet their own felt needs. An approach adopted by many intentional communities is for the group to make collective or social decisions (either by consensus or by majority rule) about economic matters that affect the community as a whole but to provide each individual member of the community with a discretionary income to use as they wish.

Marx maintained major aspects of this approach in the stage of human development that he called 'full' or 'pure' communism or just communism. The non-alienated people of this future communism will create a world in which income will be distributed on the basis of need (see Marx, K. §4); since everyone will be a productive labourer, there will no longer be any classes; and, because there will no longer be a need for political power to enforce class dominance, the state will gradually disappear to be replaced with decentralized, non-political administrative agencies. Since everyone will work, there will be high productivity and, therefore, plenty for all. Given the changed social situation, people will begin to think differently and social distinctions between occupations and between city and country will disappear. Thus, this form of

communism is, in its essentials, identical to the earliest communist tradition. At least one major twentieth-century Marxist theorist, Ernst Bloch (1885–1977) in *Das Prinzip Hoffnung* (The Principle of Hope) (1959) argued that this utopian goal should be at the centre of Marxist theory (see UTOPIANISM).

While Marxism and its version of communism predominantly took a different road, the more fundamental and historically earlier theory did not disappear. Non-Marxist forms of collective property have existed and been defended as part of the communal movement best represented by the Israeli kibbutzim and the US communal movement of the early nineteenth and mid-twentieth centuries, and by some forms of anarchism (see ANARCHISM §3). Communism as common property and as a vision of a better life for all is still a living tradition.

The arguments against communism take a number of different forms. The simplest rely on assumptions about human nature radically at variance with those of communism's proponents. The assumption is made, with little real evidence, that human beings are 'naturally' competitive and that therefore communism cannot work (see HUMAN NATURE §1). A more developed analysis argues that communism is necessarily economically inefficient and will, therefore, be unable to provide as high a standard of living as a non-communist system. Some go so far as to argue that communism is impossible to sustain over long periods of time because its inefficiency is so great that the economic system must sooner or later collapse. Of course, economic efficiency is very low in the scale of values held by most supporters of traditional communism. Proponents of communism generally take the position that economic efficiency symbolizes the competitive system that they oppose and stands in the way of the cooperative community they hope to achieve.

Today, many believe that the time of communism has passed, largely because Marxist communism has been discredited in much of the world. But communism is not, and never has been, reducible to the Marxist version. Most fundamentally, it is the economic basis for dreams of complete human fulfilment, whether it is sought in monastic orders, intentional communities or whole societies. That dream persists, and with it the ideals of communism.

COMMUNITARIANISM

See COMMUNITY AND COMMUNITARIANISM

COMMUNITY AND COMMUNITARIANISM

Reflections on the nature and significance of community have figured prominently in the history of Western ethics and political philosophy, both secular and religious. In ethics and political philosophy the term 'community' refers to a form of connection among individuals that is qualitatively stronger and deeper than a mere association. The concept of a community includes at least two elements: (1) individuals belonging to a community have ends that are in a robust sense *common*, not merely congruent private ends, and that are conceived of and valued as common ends by the members of the group; and (2) for the individuals involved, their awareness of themselves as belonging to the group is a significant constituent of their identity, their sense of who they are.

In the past two decades, an important and influential strand of secular ethical and political thought in the English-speaking countries has emerged under the banner of communitarianism. The term 'communitarianism' is applied to the views of a broad range of contemporary thinkers, including Alasdair MacIntyre, Charles Taylor, Michael Sandel, and sometimes Michael Walzer. It is important to note, however, that there is no common creed to which these thinkers all subscribe and that for the most part they avoid the term.

There are two closely related ways to characterize what communitarians have in common; one positive, the other negative. As a positive view, communitarianism is a perspective on ethics and political philosophy that emphasizes the psychosocial and ethical importance of belonging to communities, and which holds that the possibilities for justifying ethical judgments are determined by the fact that ethical reasoning must proceed within the context of a community's traditions and cultural understandings. As a negative view, communitarianism is a variety of anti-liberalism, one that criticizes liberal thought for failing to appreciate the importance of community.

At present the communitarian critique of liberalism is more developed than is communitarianism as a systematic ethical or political philosophy. Existing communitarian literature lacks anything comparable to Rawls' theory of justice or Feinberg's theory of the moral limits of criminal law, both of which are paradigmatic examples of systematic liberal ethical and political theory. For the most part, the positive content of the communitarians' views must be inferred from their criticisms of liberalism. Thus, to a large extent communitarianism so far is chiefly a way of thinking about ethics and political life that stands in fundamental opposition to liberalism. To some, communitarian thinking seems a healthy antidote to what they take to be excessive individualism and obsessive preoccupation with personal autonomy. To others, communitarianism represents a failure to appreciate the value – and the fragility – of liberal social institutions. The success of communitarianism as an ethical theory depends upon whether an account of ethical reasoning can be developed that emphasizes the importance of social roles and cultural values in the justification of moral judgments without lapsing into an extreme ethical relativism that makes fundamental ethical criticisms of one's own community impossible. The success of communitarianism as a political theory depends upon whether it can be demonstrated that liberal political institutions cannot provide adequate conditions for the flourishing of community or secure appropriate support for persons' identities in so far as their identities are determined by their membership in communities.

COMPOSITIONALITY

A language is compositional if the meaning of each of its complex expressions (for example, 'black dog') is determined entirely by the meanings of its parts ('black', 'dog') and its syntax. Principles of compositionality provide precise statements of this idea. A compositional semantics for a language is a (finite) theory which explains how semantically important properties such as truth-conditions are determined by the meanings of parts and syntax. Supposing English to have a compositional semantics helps explain how finite creatures like ourselves have the ability to understand English's infinitely many sentences. Whether human languages are in fact compositional, however, is quite controversial.

COMPUTABILITY THEORY

The effective calculability of number-theoretic functions such as addition and multiplication has always been recognized, and for that judgment a rigorous notion of 'computable function' is not required. A sharp mathematical concept was defined only in the twentieth century, when issues including the decision problem for predicate logic required a precise delimitation of functions that can be viewed as effectively calculable. Predicate logic emerged from Frege's fundamental '*Begriffsschrift*' (1879) as an expressive formal language and was described with mathematical precision by Hilbert in lectures given during the winter of 1917–18. The logical calculus Frege had also developed allowed proofs to proceed as computations in accordance with a fixed set of rules; in principle, according to Gödel, the rules could be applied 'by someone who knew nothing about mathematics, or by a machine'.

Hilbert grasped the potential of this mechanical aspect and formulated the decision problem for predicate logic as follows: 'The *Entscheidungsproblem* [decision problem] is solved if one knows a procedure that permits the decision concerning the validity, respectively, satisfiability of a given logical expression by a finite number of operations.' Some, such as, von Neumann, believed that the inherent freedom of mathematical thought provided a sufficient reason to expect a negative solution to the problem. But how could a proof of undecidability be given? The unsolvability results of other mathematical problems had always been established relative to a determinate class of admissible operations, for example, the impossibility of doubling the cube relative to ruler and compass constructions. A negative solution to the decision problem obviously required the characterization of 'effectively calculable functions'.

For two other important issues a characterization of that informal notion was also needed, namely, the general formulation of the incompleteness theorems and the effective unsolvability of mathematical problems (for example, of Hilbert's tenth problem). The first task of computability theory was thus to answer the question 'What is a precise notion of effectively calculable function?'. Many different answers invariably characterized the same class of number-theoretic functions: the partial recursive ones. Today recursiveness or, equivalently, Turing computability is considered to be the precise mathematical counterpart to 'effective calculability'. Relative to these notions undecidability results have been established, in particular the undecidability of the decision problem for predicate logic. The notions are idealized in the sense that no time or space limitations are imposed on the calculations;

the concept of 'feasibility' is crucial in computer science when trying to capture the subclass of recursive functions whose values can actually be determined.

COMPUTATIONAL THEORIES OF MIND

See MIND, COMPUTATIONAL THEORIES OF

COMPUTER SCIENCE

At first sight, computers would seem to be of minimal philosophical importance; mere symbol manipulators that do the sort of things that we can do anyway, only faster and more conveniently. Nevertheless, computers are being used to illuminate the cognitive abilities of the human and animal mind, explore the organizational principles of life, and open up new approaches to modelling nature. Furthermore, the study of computation has changed our conception of the limits and methodology of scientific knowledge.

Computers have been able to do all this for two reasons. The first is that material computing power (accuracy, storage and speed) permits the development and exploration of models of physical (and mental) systems that combine structural complexity with mathematical intransigence. Through simulation, computational power allows exploration where mathematical analysis falters. The second reason is that a computer is not merely a concrete device, but also can be studied as an abstract object whose rules of operation can be specified with mathematical precision; consequently, its strengths and limitations can be systematically investigated, exploited and appreciated. Herein lies that area of computer science of most interest to philosophers: the theory of computation and algorithms. It is here where we have learned what computers can and cannot do in principle.

JOHN WINNIE

COMTE, ISIDORE-AUGUSTE-MARIE-FRANÇOIS-XAVIER (1798–1857)

The French philosopher and social theorist Auguste Comte is known as the originator of sociology and 'positivism', a philosophical system by which he aimed to discover and perfect the proper political arrangements of modern industrial society. He was the first thinker to advocate the use of scientific procedures in the study of economics, politics and social behaviour, and, motivated by the social and moral problems caused by the French Revolution, he held that the practice of such a science would lead inevitably to social regeneration and progress.

Comte's positivism can be characterized as an approach which rejects as illegitimate all that cannot be directly observed in the investigation and study of any subject. His system of 'positive philosophy' had two laws at its foundation: a historical or logical law, 'the law of three stages', and an epistemological law, the classification or hierarchy of the sciences. The law of three stages governs the development of human intelligence and society: in the first stage, early societies base their knowledge on theological grounds, giving ultimately divine explanations for all phenomena; later, in the metaphysical stage, forces and essences are sought as explanations, but these are equally chimerical and untestable; finally, in the positive or scientific stage, knowledge is secured solely on observations, by their correlation and sequence. Comte saw this process occurring not only in European society, but also in the lives of every individual. We seek theological solutions in childhood, metaphysical solutions in youth, and scientific explanations in adulthood.

His second, epistemological law fixed a classification or hierarchy of sciences according to their arrival at the positive stage of knowledge. In order of historical development and thus of increasing complexity, these are mathematics, astronomy, physics, chemistry, biology and sociology. (Comte rejected psychology as a science, on the grounds that its data were unobservable and therefore untestable.) Knowledge of one science rested partly on the findings of the preceding science; for Comte, students must progress through the sciences in the correct order, using the simpler and more precise methods of the preceding science to tackle the more complex issues of later ones. In his six-volume *Cours de philosophie positive* (The Positive Philosophy) (1830–42), Comte gave an encyclopedic account of these sciences, ending with an exposition of what he regarded as the most advanced: social physics or 'sociology' (a term he invented). The sociologist's job would be to discover the laws that govern human behaviour on a large scale, and the ways in which social institutions and norms operate together in a complex yet ultimately predictable system.

In his later work, Comte fleshed out his vision of the positive society, describing among other things a Religion of Humanity in which historical figures would be worshipped according to their contribution to society. Despite such extravagances, however, the broader themes of his positivism – especially the idea that long-standing social problems should be approached scientifically – proved influential both

in France and, through J.S. Mill's early support, in England.

MARY PICKERING

CONCEPTS

The topic of concepts lies at the intersection of semantics and philosophy of mind. A concept is supposed to be a constituent of a thought (or 'proposition') rather in the way that a word is a constituent of a sentence that typically expresses a thought. Indeed, concepts are often thought to be the *meanings* of words (and will be designated by enclosing the words for them in brackets: [city] is expressed by 'city' and by 'metropolis'). However, the two topics can diverge: non-linguistic animals may possess concepts, and standard linguistic meanings involve conventions in ways that concepts do not.

Concepts seem essential to ordinary and scientific psychological explanation, which would be undermined were it not possible for *the same concept* to occur in different thought episodes: someone could not even recall something unless the concepts they have now overlap the concepts they had earlier. If a disagreement between people is to be more than 'merely verbal', their words must express the same concepts. And if psychologists are to describe shared patterns of thought across people, they need to advert to shared concepts.

Concepts also seem essential to categorizing the world, for example, recognizing a *cow* and classifying it as a *mammal*. Concepts are also *compositional*: concepts can be combined to form a virtual infinitude of complex categories, in such a way that someone can understand a novel combination, for example, [smallest sub-atomic particle], by understanding its constituents.

Concepts, however, are not always studied as part of psychology. Some logicians and formal semanticists study the deductive relations among concepts and propositions in abstraction from any mind. Philosophers doing 'philosophical analysis' try to specify the conditions that make something the *kind* of thing it is – for example, what it is that makes an act good – an enterprise they take to consist in the analysis of concepts.

Given these diverse interests, there is considerable disagreement about what exactly a concept is. Psychologists tend to use 'concept' for *internal representations*, for example, images, stereotypes, words that may be the vehicles for thought in the mind or brain. Logicians and formal semanticists tend to use it for *sets* of real and possible objects, and *functions* defined over them; and philosophers of mind have variously proposed *properties*, '*senses*', inferential *rules* or discrimination *abilities*.

A related issue is what it is for someone to *possess* a concept. The 'classical view' presumed concepts had 'definitions' known by competent users. For example, grasping [bachelor] seemed to consist in grasping the definition, [adult, unmarried male]. However, if definitions are not to go on forever, there must be *primitive* concepts that are not defined but are grasped in some other way. Empiricism claimed that these definitions were provided by sensory conditions for a concept's application. Thus, [material object] was defined in terms of certain possibilities of sensation.

The classical view suffers from the fact that few successful definitions have ever been provided. Wittgenstein suggested that concept possession need not consist in knowing a definition, but in appreciating the role of a concept in thought and practice. Moreover, he claimed, a concept need not apply to things by virtue of some closed set of features captured by a definition, but rather by virtue of 'family resemblances' among the things, a suggestion that has given rise in psychology to 'prototype' theories of concepts.

Most traditional approaches to possession conditions have been concerned with the *internal* states, especially the beliefs, of the conceptualizer. Quine raised a challenge for such an approach in his doctrine of 'confirmation holism', which stressed that a person's beliefs are fixed by what they find plausible overall. Separating out any particular beliefs as defining a concept seemed to him arbitrary and in conflict with actual practice, where concepts seem shared by people with different beliefs. This led Quine himself to be sceptical about talk of concepts generally, denying that there was *any* principled way to distinguish 'analytic' claims that express definitional claims about a concept from 'synthetic' ones that express merely common beliefs about the things to which a concept applies.

However, recent philosophers suggest that people share concepts not by virtue of any internal facts, but by virtue of facts about their external (social) environment. For example, people arguably have the concept [water] by virtue of interacting in certain ways with H_2O and deferring to experts in defining it. This work has given rise to a variety of *externalist* theories of concepts and semantics generally.

Many also think, however, that psychology could generalize about people's minds independently of the external contexts they happen to inhabit, and so have proposed 'two-factor theories', according to which there is an *internal* component to a concept that may play a role in psychological explanation, as

opposed to an *external* component that determines the application of the concept to the world.

CONCEPTUAL ROLE SEMANTICS

See Semantics, conceptual role

CONDILLAC, ETIENNE BONNOT DE (1715–80)

One of the leading figures of the French Enlightenment period, Condillac is the author of three highly influential books, published between 1746 and 1754, in which he attempted to refine and expand the empirical method of inquiry so as to make it applicable to a broader range of studies than hitherto. In the half-century following the publication of Newton's *Principia Mathematica* in 1687, intellectual life in Europe had been engaged upon a fierce debate between the partisans of Cartesian physics, who accepted Descartes' principles of metaphysical dualism and God's veracity as the hallmark of scientific truth, and those who accepted Newton's demonstration that the natural order constituted a single system under laws which could be known through painstaking observation and experiment. By the mid-eighteenth century Newton had gained the ascendancy, and it was the guiding inspiration of the French thinkers, known collectively as the *philosophes*, to appropriate the methods by which Newton had achieved his awesome results and apply them across a broader range of inquiries in the hope of attaining a similar expansion of human knowledge. Condillac was at the centre of this campaign.

Condillac's first book, *An Essay on the Origin of Human Knowledge* (1746), bears the subtitle *A Supplement to Mr. Locke's Essay on the Human Understanding*. While Condillac is usually seen as merely a disciple and popularizer of Locke offering little of any genuine originality, and while he did indeed agree with Locke that experience is the sole source of human knowledge, he attempted to improve on Locke by arguing that sensation alone – and not sensation together with reflection – provided the foundation for knowledge. His most famous book, the *Treatise on the Sensations* (1754), is based upon the thought-experiment of a statue whose senses are activated one by one, beginning with the sense of smell, with the intention of showing how all the higher cognitive faculties of the mind can be shown to derive from the notice the mind takes of the primitive inputs of the sense organs. Condillac also went beyond Locke in his carefully argued claims regarding the extent to which language affects the growth and reliability of knowledge. His *Treatise on Systems* (1749) offers a detailed critique of how language had beguiled the great seventeenth-century systems-builders like Descartes, Leibniz and Spinoza and led them into erroneous conceptions of the mind and human knowledge, the influence of which conceptions was as insidious as it was difficult to eradicate.

PAUL F. JOHNSON

CONDITIONALS

See Counterfactual conditionals; Indicative conditionals

CONDORCET, MARIE-JEAN-ANTOINE-NICOLAS CARITAT DE (1743–94)

The Marquis de Condorcet belongs to the second generation of eighteenth-century French *philosophes*. He was by training and inclination a mathematician, and his work marks a major stage in the development of what is known today as the social sciences. He was held in high regard by contemporaries for his contributions to probability theory, and he published a number of seminal treatises on the theory and application of probabilism. He is best known today for the *Esquisse d'un tableau historique des progrès de l'esprit humain* (1795), his monumental, secularized historical analysis of the dynamics of man's progress from the primitive state of nature to modernity.

Condorcet's principal aim was to establish a science of man that would be as concise and certain in its methods and results as the natural and physical sciences. For Condorcet there could be no true basis to science without the model of mathematics, and there was no branch of human knowledge to which the mathematical approach was not relevant. He called the application of mathematics to human behaviour and organization 'social arithmetic'.

The central epistemological assumption, upon which his philosophy was based, was that the truths of observation, whether in the context of the physical or the moral and social sciences, were nothing more than probabilities, but that their varying degrees of certainty could be measured by means of the calculus of probabilities. Condorcet was thus able, through mathematical logic, to counteract the negative implications of Pyrrhonic scepticism for the notions of truth and progress, the calculus providing not only the link between the different orders of knowledge but also the way out of the Pyrrhonic trap by demonstrating man's capacity and freedom to understand and direct the march of progress in a rationally-ordered way.

In his *Esquisse* Condorcet set out to record not only the history of man's progress through nine 'epochs', from the presocial state of nature to the societies of modern Europe, but in the tenth 'epoch' of this work he also held out the promise of continuing progress in the future. He saw the gradual emancipation of human society and the achievement of human happiness as the consequence of man having been endowed by nature with the capacity to learn from experience and of the cumulative, beneficial effects of the growth of knowledge and enlightenment. Condorcet's *Esquisse* laid the basis for the positivism of the nineteenth century, and had a particularly significant impact on the work of Saint-Simon and Auguste Comte.

CONFIRMATION THEORY

Introduction

The result of a test of a general hypothesis can be positive, negative or neutral. The first, qualitative, task of confirmation theory is to explicate these types of test result. However, as soon as one also takes individual hypotheses into consideration, the interest shifts to the second, quantitative, task of confirmation theory: probabilistically evaluating individual and general hypotheses in the light of an increasing number of test results. This immediately suggests conceiving of the confirmation of an hypothesis as increasing its probability due to new evidence.

Rudolf Carnap initiated a research programme in quantitative confirmation theory by designing a continuum of probability systems with plausible probabilistic properties for the hypothesis that the next test result will be of a certain kind. This continuum of inductive systems has guided the search for optimum systems and for systems that take analogy into account.

Carnapian systems, however, assign zero probability to universal hypotheses. Jaakko Hintikka was the first to reconsider the confirmation of such hypotheses and using Carnap's continuum for this purpose has set the stage for a whole spectrum of inductive systems of this type.

1 Qualitative and quantitative confirmation theory

According to the hypothetico-deductive method a theory is tested by examining its implications. The result of an individual test of a general hypothesis stated in observation terms can be positive, negative or neutral. If it is neutral the test was not well devised; if it is negative, the hypothesis, and hence the theory, has been falsified. *Qualitative* confirmation theory primarily aims at further explicating the intuitive notions of neutral and positive test results. Some paradoxical features discovered by Hempel and some queer predicates defined by Goodman show that this is not an easy task.

Assuming that a black raven confirms the hypothesis 'All ravens are black' and that confirmation is not affected by logically equivalent reformulations, Hempel argued that not only a non-black non-raven but, even more counterintuitively, also a black non-raven confirms it. Goodman argued that not all predicates guarantee the 'projectibility' of a universal hypothesis from observed to non-observed cases. For example, if 'grue' means 'green, if examined before *t*' and 'blue, if not examined before *t*', a green emerald discovered before *t* would not only confirm 'All emeralds are green' but also 'All emeralds are grue', and hence, assuming that consequences are also confirmed, even 'All emeralds not examined before *t* are blue'. Whereas Goodman succeeded in formulating criteria for acceptable predicates, in terms of their relative 'entrenchment' in previously successfully projected generalizations, up to now nobody has given a generally accepted qualitative solution to Hempel's riddles (see UNDERDETERMINATION).

Below we treat *quantitative*, more specifically, probabilistic confirmation theory, which aims at explicating the idea of confirmation as increasing probability due to new evidence. Carnap introduced this perspective and pointed confirmation theory towards the search for a suitable notion of logical or inductive probability (see PROBABILITY, INTERPRETATIONS OF §5). Generally speaking, such probabilities combine indifference properties with inductive properties.

2 The continuum of inductive systems

Mainly in his *The Continuum of Inductive Methods* (1952), Rudolf Carnap started a fruitful research programme centring around the famous λ-continuum. The probability systems in this programme can be described in terms of individuals and observation predicates or in terms of trials and observable outcomes. The latter way of presentation will be used here. Moreover, we will presuppose an objective probability process, although the systems to be presented can be applied in other situations as well.

Consider a hidden wheel of fortune. You are told, truthfully, only that it has precisely four coloured segments, BLUE, GREEN, RED and YELLOW, without further information about the relative size of the segments. So you do not know the objective probabilities. What you subsequently learn are only the outcomes of successive trials. Given the sequence of outcomes e_n of the first n trials, your task is to assign reasonable probabilities, $p(R/e_n)$, to the hypothesis that the next trial will result in, for example, RED.

There are several ways of introducing the λ-continuum, but the basic idea behind it is that it reflects gradually learning from experience. In fact, as Zabell rediscovered, C-systems were anticipated by Johnson. According to Carnap's favourite approach $p(R/e_n)$ should depend only on n and the number of occurrences of RED thus far, n_R. More specifically, it should be a special weighted mean of the observed relative frequency n_R/n and the (reasonable) initial probability 1/4. This turns out to leave room for a continuum of (C-)systems, the λ-continuum, $0 < \lambda < \infty$:

$$p(R/e_n) = (n_R + \lambda/4)/(n + \lambda) = n/(n + \lambda) \cdot (n_R/n) + \lambda/(n + \lambda) \cdot (1/4)$$

Note that the weights $n/(n+\lambda)$ and $\lambda/(n+\lambda)$ add up to 1 and that the larger the value of λ the slower the first increases at the expense of the second; that is, the slower one is willing to learn from experience.

C-systems have several attractive indifference, confirmation and convergence properties. The most important are as follows:

(a) order indifference or exchangeability: the resulting prior probability, $p(e_n)$, for e_n, does not depend on the order of the results of the trials, that is, $p(R/e_n) = p(e_n^*)$ for any permutation e_n^* of e_n;

(b) instantial confirmation: if e_n is followed by RED this is favourable for RED, that is, $p(R/e_nR) > p(R/e_n)$;

(c) instantial convergence: $p(R/e_n)$ approaches n_R/n for increasing n.

However, confirmation and convergence of universal hypotheses are excluded in C-systems. The reason is that C-systems in fact assign zero prior probability to all universal generalizations, for instance to the hypothesis that all results will be RED. Of course, this is desirable in the described situation, but if you were told only that there are *at most* four coloured segments, you would like to leave room for this possibility.

3 Optimum inductive systems

Carnap proved that for certain kinds of objective probability process, such as a wheel of fortune, there is an optimal value of λ, depending on the objective probabilities, in the sense that the average mistake may be expected to be lowest for this value. Surprisingly, this optimal value is independent of n. Of course, in actual research, where we do not know the objective probabilities, this optimal value cannot be calculated. Carnap did not raise the question of a reasonable estimate of the optimal value for a specific objective process, for he saw the problem of selecting a value of λ primarily as a choice that each scientist had to make in general. However, the question of a reasonable estimate has attracted the attention of other researchers.

Festa proposed basing the estimate on 'contextual' knowledge of similar processes in nature. For example, in ecology one may know the relative frequencies of certain species in different habitats before one starts the investigation of a new habitat. For a quite general class of systems, Festa formulates a solution to the estimation problem that relates the research area of confirmation theory to that of truth approximation: the optimum solution may be expected to be the most efficient way of approaching the objective or true probabilities.

Unfortunately, wheels of fortune do not constitute a technological (let alone a biological) kind for which you can use information about previously investigated instances. But if you had knowledge of a random sample of all existing wheels of fortune, Festa's approach would work on the average for a new, randomly drawn, one.

4 Inductive analogy by similarity

Carnap struggled with the question of how to include analogy considerations into inductive probabilities. His important distinction between two kinds of analogy – by similarity and by proximity – was posthumously published. Here we will consider only the first kind.

Suppose you find GREEN more similar to BLUE than to RED. Carnap's intuition of analogy by similarity is that, for instance, the posterior

probability of GREEN should be higher if, other things being equal, some occurrences of RED are replaced by occurrences of BLUE. The background intuition, not valid for artificial wheels of fortune, is that similarity in one respect (for example, colour) will go together with similarities in other respects (for example, objective probabilities). However, explicating which precise principle of analogy one wants to fulfil has turned out to be very difficult.

One interesting approach is in terms of *virtual trials*, which is a way of determining how analogy influence is to be distributed after n trials. In the case above, BLUE would get more analogy credits than RED from an occurrence of GREEN. The resulting systems of virtual analogy have the same confirmation and convergence properties as C-systems. Moreover, they satisfy a principle of analogy that is in general more plausible than Carnap's. Roughly, the new principle says that replacement of a previous occurrence of BLUE by GREEN makes less difference for the probability that the next trial will be BLUE than does replacement of a previous occurrence of RED by GREEN for the probability that the next trial will be RED.

Unfortunately, systems of virtual analogy are not exchangeable: the order of results makes a difference. There are, however, exchangeable systems with some kind of analogy by similarity. For example, Skyrms has sketched a Bayesian approach that uses information about possible gravitational bias of a symmetric wheel of fortune to determine the influence of analogy, and di Maio follows a suggestion of Carnap.

5 Universal generalizations

Carnap was well aware that C-systems do not leave room for non-analytic universal generalizations. In fact, all systems presented thus far have this problem. Although tolerant of other views, Carnap himself was inclined to downplay the theoretical importance of universal statements.

Hintikka took up the problem of universal statements. His basic idea was to apply Bayesian conditionalization to Carnap's C-systems with uniform λ, using a specific prior distribution on universal statements containing a parameter α. The systems belonging to the resulting α-λ-continuum have the instantial confirmation and convergence properties and also the desired property of universal confirmation; that is, that the probability of a not yet falsified universal statement increases with another instance of it. Moreover, they satisfy universal convergence: $p(H_R/e_n)$ approaches 1 for increasing n as long as only RED continues to occur (where H_R indicates the universal statement that only RED will occur in the long run). For increasing parameter α, universal confirmation is smaller and universal convergence slower.

In fact, systems based on an arbitrary prior distribution and C-systems with arbitrary λ, here called H-systems, already have the general properties of instantial and universal confirmation and convergence. The subclass of H-systems based on an arbitrary prior distribution and C-systems with λ proportional to the corresponding number of possible outcomes is particularly interesting. For this subclass appears to be co-extensive with a class of systems introduced by Hintikka and by Niiniluoto, very differently from H-systems, using principles and parameters related only to finite sequences of outcomes.

There is also a plausible 'delabelled' reformulation of H-systems that can be extended to the very interesting case of an unknown denumerable number of possible outcomes. Presenting the delabelling in terms of exchangeable partitions, Zabell has studied this case by principles leading to a class of systems with three parameters.

6 Applications

The Carnap–Hintikka programme in confirmation theory, also called inductive probability theory, has applications in several directions. Systems of inductive probability were intended primarily for explicating confirmation as increasing probability. One may even define a quantitative degree of confirmation: namely, as the difference or ratio of the posterior and the initial or prior probability. There are other interesting types of application as well. Carnap and Stegmüller stressed that they can be used in decision-making, and Skyrms applies them in game theory (see Decision and game theory). Costantini *et al.* use them in a rational reconstruction of elementary particle statistics. Festa suggests several areas of empirical science where optimum inductive systems can be used. Finally, for universal hypotheses, Hintikka, Hilpinen and Pietarinen use systems of inductive probability to formulate rules of acceptance and Niiniluoto uses these systems to estimate degrees of verisimilitude.

CONFUCIAN ANALECTS

See CONFUCIUS

CONFUCIAN PHILOSOPHY, CHINESE

Chinese Confucian philosophy is primarily a set of ethical ideas oriented toward practice. Characteristically, it stresses the traditional boundaries of ethical responsibility and *dao*, or the ideal of the good human life as a whole. It may be characterized as an ethics of virtue in the light of its conception of *dao* and *de* (virtue). Comprising the conceptual framework of Confucian ethics are notions of basic virtues such as *ren* (benevolence), *yi* (rightness, righteousness), and *li* (rites, propriety). There are also notions of dependent virtues such as filiality, loyalty, respectfulness and integrity. Basic virtues are considered fundamental, leading or action-guiding, cardinal and the most comprehensive. In the classic Confucian sense, *ren* pertains to affectionate concern for the well-being of fellows in one's community. Notably, *ren* is often used in an extended sense by major Song and Ming Confucians as interchangeable with *dao* for the ideal of the universe as a moral community. *Yi* pertains to the sense of rightness, especially exercised in coping with changing circumstances of human life, those situations that fall outside the scope of *li*. *Li* focuses on rules of proper conduct, which have three functions: delimiting, supportive and ennobling. That is, the *li* define the boundaries of proper behaviour, provide opportunities for satisfying desires of moral agents within these boundaries, and encourage the development of noble characters which markedly embody cultural refinement and communal concerns. The *li* are the depository of insights of the Confucian tradition as a living ethical tradition. This tradition is subject to changing interpretation governed by the exercise of *quan* or the weighing of circumstances informed by the sense of rightness (*yi*).

However, the common Confucian appeal to historical events and paradigmatic individuals is criticized because of lack of understanding of the ethical uses of such a historical appeal. The pedagogical use stresses the study of the classics in terms of the standards of *ren*, *yi* and *li*. Learning, however, is not a mere acquisition of knowledge, but requires understanding and insight. Also, the companion study of paradigmatic individuals is important, not only because they point to models of emulation but also because they are, so to speak, exemplary personifications of the spirits of *ren*, *yi* and *li*. Moreover, they also function as reminders of moral learning and conduct that appeal especially to what is deemed in the real interest of the learner. The rhetorical use of the historical appeal is basically an appeal to plausible presumptions, or shared beliefs and trustworthiness. These presumptions are subject to further challenge, but they can be accepted as starting points in discourse. The elucidative use of historical appeal purports to clarify the relevance of the past for the present. Perhaps most important for argumentative discourse is the evaluative function of historical appeal. It focuses our knowledge and understanding of our present problematic situations as a basis for exerting the unexamined claims based on the past as a guidance for the present. Thus, both the elucidative and evaluative uses of historical appeal are critical and attentive to evidential grounding of ethical claims.

Because of its primary ethical orientation and its influence on traditional Chinese life and thought, Confucianism occupies a pre-eminent place in the history of Chinese philosophy. The core of Confucian thought lies in the teachings of Confucius (551–479 BC) contained in the *Analects* (*Lunyu*), along with the brilliant and divergent contributions of Mencius (372?–289 BC) and Xunzi (*fl.* 298–238 BC), as well as the *Daxue* (Great Learning) and the *Zhongyong* (Doctrine of the Mean), originally chapters in the *Liji* (Book of Rites). Significant and original developments, particularly along a quasi-metaphysical route, are to be found in the works of Zhou Dunyi (1017–73), Zhang Zai (1020–77), Cheng Hao (1032–85), Cheng Yi (1033–1107), Zhu Xi (1130–1200), Lu Xiangshan (1139–93), and Wang Yangming (1472–1529). Li Gou (1009–59), Wang Fuzhi (1619–92), and Dai Zhen (1723–77) have also made noteworthy contributions to the critical development of Confucian philosophy. In the twentieth century, the revitalization and transformation of Confucian philosophy has taken a new turn in response to Western philosophical traditions. Important advances have been made by Feng Youlan, Tang Junyi, Thomé H. Fang, and Mou Zongsan. Most of the recent works in critical reconstruction are marked by a self-conscious concern with analytic methodology and the relevance of existentialism, phenomenology, and hermeneutics. Still lacking is a comprehensive and systematic Confucian theory

informed by both the history and the problems of Western philosophy.

A.S. CUA

CONFUCIUS (551–479 BC)

Confucius is arguably the most influential philosopher in human history – 'is' because, taking Chinese philosophy on its own terms, he is still very much alive. Recognized as China's first teacher both chronologically and in importance, his ideas have been the rich soil in which the Chinese cultural tradition has grown and flourished. In fact, whatever we might mean by 'Chineseness' today, some two and a half millennia after his death, is inseparable from the example of personal character that Confucius provided for posterity. Nor was his influence restricted to China; all of the Sinitic cultures – especially Korea, Japan and Vietnam – have evolved around ways of living and thinking derived from the wisdom of the Sage.

A couple of centuries before Plato founded his Academy to train statesmen for the political life of Athens, Confucius had established a school with the explicit purpose of educating the next generation for political leadership. As his curriculum, Confucius is credited with having over his lifetime edited what were to become the Chinese Classics, a collection of poetry, music, historical documents and annals that chronicled the events at the Lu court, along with an extensive commentary on the *Yijing* (Book of Changes). These classics provided a shared cultural vocabulary for his students, and became the standard curriculum for the Chinese literati in subsequent centuries.

Confucius began the practice of independent philosophers travelling from state to state in an effort to persuade political leaders that their particular teachings were a practicable formula for social and political success. In the decades that followed the death of Confucius, intellectuals of every stripe – Confucians, Legalists, Mohists, Yin–Yang theorists, Militarists – would take to the road, attracted by court academies which sprung up to host them. Within these seats of learning, the viability of their various strategies for political and social unity would be hotly debated.

CONNECTIONISM

Connectionism is an approach to computation that uses connectionist networks. A connectionist network is composed of information-processing units (or nodes); typically, many units process information simultaneously, giving rise to massively 'parallel distributed processing'. Units process information only locally: they respond only to their specific input lines by changing or retaining their activation values; and they causally influence the activation values of their output units by transmitting amounts of activation along connections of various weights or strengths. As a result of such local unit processing, networks themselves can behave in rule-like ways to compute functions.

The study of connectionist computation has grown rapidly since the early 1980s and now extends to every area of cognitive science. For the philosophy of psychology, the primary interest of connectionist computation is its potential role in the computational theory of cognition – the theory that cognitive processes are computational. Networks are employed in the study of perception, memory, learning and categorization; and it has been claimed that connectionism has the potential to yield an alternative to the classical view of cognition as rule-governed symbol manipulation.

Since cognitive capacities are realized in the central nervous system, perhaps the most attractive feature of the connectionist approach to cognitive modelling is the neural-like aspects of network architectures. The members of a certain family of connectionist networks, artificial neural networks, have proved to be a valuable tool for investigating information processing within the nervous system. In artificial neural networks, units are neuron-like; connections, axon-like; and the weights of connections function in ways analogous to synapses.

Another attraction is that connectionist networks, with their units sensitive to varying strengths of multiple inputs, carry out in natural ways 'multiple soft constraint satisfaction' tasks – assessing the extent to which a number of non-mandatory, weighted constraints are satisfied. Tasks of this sort occur in motor-control, early vision, memory, and in categorization and pattern recognition. Moreover, typical networks can re-programme themselves by adjusting the weights of the connections among their units, thereby engaging in a kind of 'learning'; and they can do so even on the basis of the sorts of noisy and/or incomplete data people typically encounter.

The potential role of connectionist architectures in the computational theory of cognition is, however, an open question. One possibility is that cognitive architecture is a 'mixed architecture', with

classical and connectionist modules. But the most widely discussed view is that cognitive architecture is thoroughly connectionist. The leading challenge to this view is that an adequate cognitive theory must explain high-level cognitive phenomena such as the systematicity of thought (someone who can think 'The dog chases the cat' can also think 'The cat chases the dog'), its productivity (our ability to think a potential infinity of thoughts) and its inferential coherence (people can infer 'p' from 'p and q'). It has been argued that a connectionist architecture could explain such phenomena only if it implements a classical, language-like symbolic architecture. Whether this is so, however, and, indeed, even whether there *are* such phenomena to be explained, are currently subjects of intense debate.

CONSCIOUSNESS

Philosophers have used the term 'consciousness' for four main topics: knowledge in general, intentionality, introspection (and the knowledge it specifically generates) and phenomenal experience. Here we discuss the last two uses. Something within one's mind is 'introspectively conscious' just in case one introspects it (or is poised to do so). Introspection is often thought to deliver one's primary knowledge of one's mental life. An experience or other mental entity is 'phenomenally conscious' just in case there is 'something it is like' for one to have it. The clearest examples are: perceptual experiences, such as tastings and seeings; bodily-sensational experiences, such as those of pains, tickles and itches; imaginative experiences, such as those of one's own actions or perceptions; and streams of thought, as in the experience of thinking 'in words' or 'in images'. Introspection and phenomenality seem independent, or dissociable, although this is controversial.

Phenomenally conscious experiences have been argued to be nonphysical, or at least inexplicable in the manner of other physical entities. Several such arguments allege that phenomenal experience is 'subjective'; that understanding some experiences requires undergoing them (or their components). The claim is that any objective physical science would leave an 'explanatory gap', failing to describe what it is like to have a particular experience and failing to explain why there are phenomenal experiences at all. From this, some philosophers infer 'dualism' rather than 'physicalism' about consciousness, concluding that some facts about consciousness are not wholly constituted by physical facts. This dualist conclusion threatens claims that phenomenal consciousness has causal power, and that it is knowable in others and in oneself.

In reaction, surprisingly much can be said in favour of 'eliminativism' about phenomenal consciousness; the denial of any realm of phenomenal objects and properties of experience. Most (but not all) philosophers deny that there are phenomenal objects – mental images with colour and shape, pain-objects that throb or burn, inner speech with pitch and rhythm, and so on. Instead, experiences may simply seem to involve such objects. The central disagreement concerns whether these experiences have phenomenal properties – 'qualia'; particular aspects of what experiences are like for their bearers. Some philosophers deny that there are phenomenal properties – especially if these are thought to be intrinsic, completely and immediately introspectible, ineffable, subjective or otherwise potentially difficult to explain on physicalist theories. More commonly, philosophers acknowledge qualia of experiences, either articulating less bold conceptions of qualia, or defending dualism about boldly conceived qualia.

Introspective consciousness has seemed less puzzling than phenomenal consciousness. Most thinkers agree that introspection is far from complete about the mind and far from infallible. Perhaps the most familiar account of introspection is that, in addition to 'outwardly perceiving' non-mental entities in one's environment and body, one 'inwardly perceives' one's mental entities, as when one seems to see visual images with one's 'mind's eye'. This view faces several serious objections. Rival views of introspective consciousness fall into three categories, according to whether they treat introspective access (1) as epistemically looser or less direct than inner perception, (2) as tighter or more direct, or (3) as fundamentally non-epistemic or nonrepresentational. Theories in category (1) explain introspection as always retrospective, or as typically based on self-directed theoretical inferences. Rivals from category (2) maintain that an introspectively conscious mental state reflexively represents itself, or treat introspection as involving no mechanism of access at all. Category (3) theories treat a mental state as introspectively conscious if it is distinctively available for linguistic or rational processing, even if it is not itself perceived or otherwise thought about.

ERIC LORMAND

CONSENT

A concept of central importance in moral, political and legal philosophy, consent is widely recognized as justifying or legitimating acts, arrangements or expectations. In standard cases, a person's consent to another person's acts removes moral or legal objections to or liability for the performance of those acts. Thus, in medical practice the informed consent of a patient to a procedure can justify the physician's actions. In law, the maxim '*volenti non fit injuria*' (the willing person is not wronged) governs a wide range of acts and transactions, from the economic to the sexual. And in politics, it is often supposed that it is 'the consent of the governed' that justifies or makes permissible both governmental policies and the use of official coercion to compel obedience to law. Consent may be given in a variety of more and less direct forms, but its binding force always rests on the satisfaction of conditions of knowledge, intention, competence, voluntariness and acceptability of content.

A. JOHN SIMMONS

CONSEQUENTIALISM

Introduction

Consequentialism assesses the rightness or wrongness of actions in terms of the value of their consequences. The most popular version is act-consequentialism, which states that, of all the actions open to the agent, the right one is that which produces the most good.

Act-consequentialism is at odds with ordinary moral thinking in three respects. First, it seems excessively onerous, because the requirement to make the world a better place would demand all our time and effort; second, it leaves no room for the special duties which we take ourselves to have to those close to us – family, friends and fellow citizens; and third, it might require us, on occasion, to do dreadful things in order to bring about a good result.

Consequentialists standardly try to bring their theory more into line with common thinking by amending the theory in one of two ways. Indirect act-consequentialism holds that we should not necessarily aim to do what is right. We may get closer to making the world the best possible place by behaviour which accords more with ordinary moral thought. Rule-consequentialism holds that an action is right if it is in accordance with a set of rules whose general acceptance would best promote the good. Such rules will bear a fairly close resemblance to the moral rules under which we now operate.

1 Act-consequentialism

Although the term 'consequentialism' is a recent coinage – it appears to have first been used in its present sense by Anscombe – it refers to a type of theory which has a long history. Consequentialism builds on what may seem to be the merest truism, namely that morality is concerned with making the world a better place for all. Consequentialist considerations certainly figure importantly in issues of public policy. Penal, economic or educational programmes are standardly judged by the goodness or badness of their results.

All moral theories offer an account both of the right and of the good. They all tell us, that is, both what makes an action right or wrong, and what kinds of thing are good or valuable. It is characteristic of consequentialist theories to assess whether an action is right in terms of the amount of good it produces (see §4). Deontological ethical theories, by contrast, hold that the right is independent of the good: certain kinds of action are wrong, and others right, independently of the goodness or badness of their consequences (see Deontological ethics; Right and good).

Act-consequentialism, the simplest form of the theory, holds that the right action – the one you should do – is the one which would produce the greatest balance of good over bad consequences; that is, the one which would maximize the good. (Where two or more actions come out equal best, then it is right to do any one of them.) Which action is in fact the right one will depend on what account of the good any particular act-consequentialist theory offers.

A theory of the good is an account of those things which are intrinsically good, good in themselves, and not merely good as a means to something else which is good (see Good, theories of the). A visit to the dentist is only extrinsically good, because it leads to healthy teeth and the avoidance of toothache, but it is not in itself a good thing; it is a necessary evil. By far the most popular and influential account of the good within the consequentialist camp is that offered by utilitarianism (see Utilitarianism). On this view, usually known as hedonism or welfarism, the good is

pleasure, happiness or wellbeing (see HEDONISM; HAPPINESS). The act-utilitarian holds, therefore, that the right action is the one which maximizes happiness.

Many consequentialists reject hedonism. A pioneer in this respect was G.E. MOORE, whose theory, somewhat confusingly, used to be referred to as ideal utilitarianism, in contrast to the hedonistic variety. Among the things which have been held to be intrinsically good are knowledge, virtue, beauty, justice, and the flourishing of the environment as a whole. Many of these alternative accounts of the good are pluralist: that is, they claim that there are several different kinds of good thing which cannot all be brought under one heading. Pluralist act-consequentialism faces a difficulty. In order to determine which of the possible actions is the right one, agents must be able to rank the outcomes of each action, from the worst to the best. But if there are several distinct values which cannot be reduced to a common measure, how can one kind of value be compared with another in order to produce a definitive ranking? This is the problem of incommensurability of value.

The term 'consequentialism', though hallowed by frequent philosophical use, may be misleading since it might naturally be taken to imply that an action itself can have no intrinsic value; its value is all to be found in its consequences. Utilitarianism is indeed committed to this view – for what matters on the utilitarian account is not the nature of the act itself but the pleasure which it produces in anyone affected by it – but it is not an essential feature of consequentialism as such. Some consequentialists wish to leave room for the thought that certain kinds of action, such as lying, cheating, and killing the innocent, are intrinsically bad, while other kinds of act, such as generous, loyal, or just ones, are intrinsically good. Consequentialism can take such values into account in calculating which course of action produces the best results. In deciding whether one course of action is preferable to another, a consequentialist needs to know the total value that would be produced by taking each course of action, and that will include not only the value of the consequences but the value, if any, which attaches to the action itself.

Consequentialism is sometimes described as a teleological theory, because it conceives of a moral theory as setting a goal which we should strive to achieve (see TELEOLOGICAL ETHICS). The goal which consequentialism sets is to bring about a world containing the greatest balance of good over bad. Such a classification risks confusion, however, since a virtue ethics, such as Aristotle's, is also usually classified as teleological, yet Aristotle's theory differs from consequentialism in at least two crucial respects. First, the good at which agents aim, on Aristotle's view (outlined in *Nicomachean Ethics*), is not the best state of the world, but the good life for humans; agents are to seek to realize distinctively human goods in their own lives. Second, Aristotle's theory, unlike consequentialism, does not define the right in terms of the good. On the contrary, a full understanding of the good life rests on a prior conception of the right, for an important part of the good life consists in acting rightly (see ARISTOTLE §§21–6; RIGHT AND GOOD; VIRTUE ETHICS).

We also need to distinguish the kind of consequentialism with which we are here concerned from ethical egoism, which is sometimes classified as a consequentialist theory (see EGOISM AND ALTRUISM). Ethical egoism, which holds that the right action is the one which would best promote the agent's own interests, is structurally similar to consequentialism in that the right action is the one which maximizes a good, in this case, the agent's own good. What distinguishes egoism from the sort of consequentialism discussed here is that the latter is an *impartial* theory, giving equal weight to each person's good (see IMPARTIALITY).

2 Criticisms of act-consequentialism

How should consequentialists set about deciding what to do? A natural answer is: by calculating, as best they may, what would produce the most good on any particular occasion when they are called upon to act. Of course, lack of time and knowledge limit what consequentialists can do by way of calculation, but they must do the best they can. So interpreted, however, act-consequentialism can be criticized for running counter to our intuitive moral convictions in a number of ways.

First, it seems excessively demanding; I shall only be acting rightly in so far as I maximize the good. Given all the bad things in the world, and the fact that few of us do much to improve them, it is clear that, in order to do what act-consequentialism requires, I would have to devote virtually all my energy and resources to making the world a better place. This would give me no time or money to pursue my own interests, or even to relax, except to refresh me ready to redouble my moral efforts on the morrow. The degree of self-sacrifice required would make the lives of the saints look self-indulgent. Ordinary morality is surely not as demanding as this; it gives us permission to pursue our own goals, provided that we are not in breach of any of our fundamental duties. Some have proposed, in order to meet this point, that the theory be modified so that an act is right if its consequences are good, or good enough, even if they are not the

best. This suggestion has not been widely adopted, for it is usually held that a rational agent will always prefer the greater good to the less.

Second, act-consequentialism appears to leave no place for the duties we take ourselves to have to our family and friends (see FAMILY, ETHICS AND THE; FRIENDSHIP). Such duties are often classified as agent-relative: each of us should help *their own* family and friends, so that the persons to whom the duties are owed vary from agent to agent. Act-consequentialism, however, is an agent-neutral moral theory; the goal at which we should aim does not depend on who the agent is. I should direct my efforts towards those for whom I can do the most good; their relationship to me is irrelevant. Even if act-consequentialism places special value on the cultivation of certain relationships, such as friendship, this will still not yield a duty of friendship, as traditionally understood. If friendship is a great good, then my duty as a consequentialist is to promote friendship in general between all persons; that will not necessarily require me to give special attention to *my* friends, as distinct from helping others to give special attention to their friends.

Third, if act-consequentialism is too demanding in one respect it seems too permissive in another. For it leaves no room for the thought, central to much ordinary moral thinking, that there are certain constraints on our action, certain kinds of act, such as cheating, torturing and killing, which we ought not to contemplate, even if acting in one of these forbidden ways would maximize the good. The end, as we often say, does not justify the means. Once again, constraints seem to be agent-relative. Each of us is required not to kill or torture the innocent *ourselves* even if, by doing so, we could prevent two such tortures or killings.

3 Indirect act-consequentialism

Because it generates these counter-intuitive results, few consequentialists hold that agents should decide what to do by asking what will produce the best results. There are two theories which offer a less direct link between the overall goal of making things go as well as possible and how one should decide to act on any particular occasion. The first of these is known as indirect act-consequentialism. It retains the claim that the right action is the one with the best consequences, but denies that the virtuous agent needs be guided directly by consequentialist thoughts when deciding how to act.

Indirect act-consequentialism builds on the thought that we do not necessarily hit the target if we aim directly at it. The gunner must make allowances for wind, gravity and poorly aligned sights; the moralist may have to direct our thoughts away from the goal if we are to achieve it. Act-consequentialism, on this view, tells us what the target is, but not how to hit it. It is not itself a good guide to action for a number of reasons: the calculations are tricky and time-consuming; we may be tempted to skew the results in our favour; doing the right action may require us to go against dispositions which are both deeply rooted and generally useful. So we may actually do better, in terms of achieving the goals which consequentialism sets us, if we do not aim to do what is right, but follow a few fairly simple moral rules of the traditional type, or encourage within ourselves the development of dispositions, such as kindness and loyalty, which will normally lead us to act in beneficial ways. In adopting such rules, or developing such dispositions, we know that we will sometimes act wrongly when we could, perhaps, have acted rightly. Yet we may still get closer, in the long run, to achieving the consequentialist goal than we would have if we had attempted to aim at it directly.

Some indirect act-consequentialists go further. Since we make better decisions if we eschew consequentialist calculations, it might be best if we rejected consequentialism. It seems possible that agents might behave worse, in consequentialist terms, if they were taught the truth of consequentialism than if they were brought up to believe some other moral theory. In which case consequentialists would do well to prevent its truth being generally known. Opponents see this position as incoherent. If the adoption of consequentialism demands its suppression then in what sense can we adopt it? How could a society be said to be governed by a moral code if no-one in that society believed it?

4 Rule-consequentialism

The second alternative to direct act-consequentialism is rule-consequentialism, which offers a more substantive role for moral rules or principles. Individual acts are judged right or wrong by reference to the rules; the rules, but not the individual acts, are judged by the results of accepting them. The right action is, roughly, the one that is in conformity with a set of moral rules which, if generally accepted, would tend to produce better results than any other set of viable rules we might accept. Rule-consequentialism differs from indirect act-consequentialism in two ways. It maintains that each decision should be guided by thoughts about which action is the right one, and denies that the right action is necessarily the one with the best results. In deciding which rules to accept we should bear in mind that the rules need to

be clear, reasonably simple and not too difficult to comply with, given human nature. If they meet these requirements, it is likely that such rules will not be too dissimilar to our present ones.

Rule-consequentialism might be a plausible moral theory, but should it properly be seen as a form of consequentialism? It apparently abandons a central tenet of consequentialism: the claim that our goal should be to maximize the good. The rule I should follow, on this view, is the one that *would* have better consequences, if generally accepted, than any other rule. If it is not, in fact, generally accepted, then in following it I may not get as close to maximizing the good as I would if I followed some other policy. For that reason, perhaps, act-consequentialism has remained most popular among defenders of the theory, despite its difficulties.

DAVID MCNAUGHTON

CONSERVATISM

Conservatism is an approach to human affairs which mistrusts both a priori reasoning and revolution, preferring to put its trust in experience and in the gradual improvement of tried and tested arrangements. As a conscious statement of position, it dates from the reaction of Burke and de Maistre to the Enlightenment and Revolutionary thought and practices in the eighteenth century. Its roots, however, go far deeper. From Plato, conservatives derive a sense of the complexity and danger of human nature, although they reject emphatically his belief in the desirability of philosophical governance. From Aristotle, conservatives derive their sense of the need for practical experience in judging both moral and political matters, and their understanding of the role of tradition in inculcating habits of virtue and wisdom in the young.

Against Plato, conservatives prefer the limited government advocated by Hobbes, because of their belief in the ignorance and corruptibility of rulers, and because of their wish to encourage the self-reliance of subjects. They do, however, reject any conception of a social contract. In this, they follow de Maistre, who argued that creatures with the institutions and reactions necessary to form a social contract will already be in a society and hence have no need of such a thing.

While de Maistre emphasized the terror underlying political power, more characteristic of modern Anglo-Saxon conservatism is the position of Burke. For Burke, a good constitution is one adorned with ‘pleasing illusions’ to make ‘power gentle and obedience liberal’. It is also one which dissipates power in a society through autonomous institutions independent of the state. For both these reasons the communist regimes of eastern Europe could not be defended by conservatives, even though for a time they represented a form of social order.

While conservatism is not antithetical to the free market, and while the market embodies virtues the conservative will approve of, for the conservative the market needs to be supplemented by the morality, the institutions and the authority necessary to sustain it. Human beings are by nature political, and also inevitably derive their identity from the society to which they belong. Our sense of self is established through our family relationships and also through the wider recognition and apportionment of roles we achieve in the public world beyond the family. According to Hegel, who since Aristotle has written most profoundly on the interplay of the private and the public in human life, both family and the public world of civil society need to be sustained through the authority of the state. On the other hand, the distinctions between family, civil society and the state need to be maintained against the characteristically modern tendency to treat them collectively. In his insistence both on authority and on the checks and balances needed in a good society, Hegel may be said to be the most articulate and systematic of conservative thinkers.

Conservatism has been much criticized for its tendency towards complacency and to accept the status quo even when it is unacceptable. However, in its stress on the imperfectibility of human nature and on the dangers of wholesale revolution, it may be said to be more realistic than its opponents. Conservatives can also be quite content with the claim that societies animated by conservative political structures have been more successful morally and materially than socialist or liberal societies. This claim they believe to be true, and it is a fundamental aspect of their position that the dispute between them and their opponents is, at bottom, an empirical one.

CONSTITUTIONALISM

Constitutionalism comprises a set of ideas, principles and rules, all of which deal with the question of how to develop a political system which excludes as far as possible the chance of arbitrary rule. While according to one of the classic sources of constitutionalism, article sixteen of the 1789 French Declaration of the Rights of Man and of the Citizen, 'any society in which rights are not guaranteed, or in which the separation of powers is not defined, has no constitution', the scope of constitutional principles is in fact broader. In addition to these two defining principles, the following are essential: popular sovereignty; the rule of law; rules about the selection of power-holders and about their accountability to the ruled; and principles about the making, unmaking, revision, interpretation and enforcement of a constitution. Despite close affiliations, constitutionalism and democracy are not the same. Whereas democracy is an institutional device which realizes the right of the people to govern themselves, constitutionalism aims to establish institutional restraints on the power of the rulers, even if they are popularly elected and legitimized. Constitutionalism embodies the self-rationalizing and self-restraining principles of popular government.

ULRICH K. PREUß

CONSTRUCTIVISM

Originally proposed by sociologists of science, constructivism or social constructivism is a view about the nature of scientific knowledge held by many philosophers of science. Constructivists maintain that scientific knowledge is made by scientists and not determined by the world. This makes constructivists antirealists. Constructivism here should not be confused with constructivism in mathematics or logic, although there are some similarities. Constructivism is more aptly compared with Berkeley's idealism.

Most constructivist research involves empirical study of a historical or a contemporary episode in science, with the aim of learning how scientists experiment and theorize. Constructivists try not to bias their case studies with presuppositions about how scientific research is directed. Thus their approach contrasts with approaches in philosophy of science that assume scientists are guided by a particular method. From their case studies, constructivists have concluded that scientific practice is not guided by any one set of methods. Thus constructivism is relativist or antirationalist.

There are two familiar (and related) criticisms of constructivism. First, since constructivists are self-avowed relativists, some philosophers argue that constructivism fails for the same reasons that relativism fails. But many philosophers of science note that relativism can be characterized in various ways and that versions of relativism can be useful in the interpretation of science. Therefore, constructivism's relativism does not by itself render it unacceptable. Second, constructivists are accused of believing that scientists literally 'make the world', in the way some make houses or cars. This is probably not the best way to understand constructivism. Rather, constructivism requires only the weaker thesis that scientific knowledge is 'produced' primarily by scientists and only to a lesser extent determined by fixed structures in the world. This interprets constructivism as a thesis about our access to the world via scientific representations. For example, constructivists claim that the way we represent the structure of DNA is a result of many interrelated scientific practices and is not dictated by some ultimate underlying structure of reality. Constructivist research provides important tools for epistemologists specializing in the study of scientific knowledge.

STEPHEN M. DOWNES

CONTENT, NON-CONCEPTUAL

To say that a mental state has intentional content is to say that it represents features of the world. The intentional content of a belief can be characterized in terms of concepts: the content of the belief that fish swim is characterized by the concepts 'fish' and 'swimming'. The contents of beliefs are, for this reason, often described as conceptual. One way to explain this idea is to say that to have a belief, one has to possess the concepts which characterize the belief's content. However, some philosophers believe that certain mental states have non-conceptual contents: these states represent the world without the subject having to possess the concepts which characterize their contents. The main examples of these putative states are conscious perceptual experiences and the non-conscious states of cognitive information-processing systems (such as the visual system).

TIM CRANE

CONTENT: WIDE AND NARROW

A central problem in philosophy is to explain, in a way consistent with their causal efficacy, how mental states can represent states of affairs in the world. Consider, for example, that wanting water and thinking there is some in the tap can lead one to turn on the tap. The contents of these mental states pertain to things in the world (water and the tap), and yet it would seem that their causal efficacy should depend solely on their internal characteristics, not on their external relations. That is, a person could be in just those states and those states could play just the same psychological roles, even if there were no water or tap for them to refer to. However, certain arguments, based on some imaginative thought experiments, have persuaded many philosophers that thought contents do depend on external factors, both physical and social. A tempting solution to this dilemma has been to suppose that there are two kinds of content, wide and narrow. Wide content comprises the referential relations that mental states bear to things and their properties. Narrow content comprises the determinants of psychological role. Philosophers have debated whether both notions of content are viable and, if so, how they are connected.

CONTEXTUALISM, EPISTEMOLOGICAL

The idea that norms vary with social setting has long been recognized, but it is only in the late twentieth century that philosophers have developed precise versions of epistemological contextualism, the theory that standards of knowledge and justification vary with context. Ordinary practice seems to support this rather than the 'invariantist' view that epistemological standards are uniform.

Suppose, for example, that having seen my children a minute ago, I assert 'I know my children are in the garden'. My neighbour Harold then says, 'Good, because an escaped prisoner is seeking hostages nearby'. I may then appropriately claim, 'On second thoughts, I do not know, I should check carefully'. Standards for knowledge appear to have shifted, since they now require further investigation.

Contextualism's greatest advantage is its response to scepticism. Sceptics raise radical possibilities, such as that we might be dreaming. The contextualist grants that such doubts are legitimate in the sceptical context, but holds they are illegitimate in everyday situations. Yet contextualism can appear to be an objectionable form of relativism, and may be accused of confusing standards that we apply in practical conversational contexts with the true standards that determine whether someone has knowledge.

CONTINUANTS

There is a common-sense distinction between terms such as 'statue' or 'chair' on the one hand, and 'concert' or 'war' on the other. A long-standing tradition in metaphysics has attached some significance to this distinction, holding that the first kind of term is used to name continuants, whereas the second kind is used to name events or processes. The difference is that continuants can be said to change, and therefore persist through change, whereas events do not. However, the distinction between continuants and events has been challenged on the grounds that no concrete object does, in fact, retain its identity through time. It has been suggested, for example, that unless we give up the notion of identity through time, we are faced with questions that we cannot answer. In addition, the notion that things persist through change is, apparently, threatened by a certain view of time. On this view there is in reality no past, present and future, but rather unchanging temporal relations between events. It has been suggested that such a view is committed to the idea that objects have temporal parts, and these by definition cannot persist through time.

ROBIN LE POIDEVIN

CONTINUUM HYPOTHESIS

The 'continuum hypothesis' (CH) asserts that there is no set intermediate in cardinality ('size') between the set of real numbers (the 'continuum') and the set of natural numbers. Since the continuum can be shown to have the same cardinality as the power set (that is, the set of subsets) of the natural numbers, CH is a special case of the 'generalized continuum hypothesis' (GCH), which says that for any infinite set, there is no set intermediate in cardinality between it and its power set.

Cantor first proposed CH believing it to be true, but, despite persistent efforts, failed to prove it. König proved that the cardinality of the continuum cannot be the sum of denumerably many smaller cardinals, and it has been shown that this is the only restriction the accepted axioms of set theory place on its cardinality. Gödel showed that CH was consistent with these axioms and Cohen that its

negation was. Together these results prove the independence of CH from the accepted axioms.

Cantor proposed CH in the context of seeking to answer the question 'What is the identifying nature of continuity?' These independence results show that, whatever else has been gained from the introduction of transfinite set theory – including greater insight into the import of CH – it has not provided a basis for finally answering this question. This remains the case even when the axioms are supplemented in various plausible ways.

CONTRACTARIANISM

The idea that political relations originate in contract or agreement has been applied in several ways. In Plato's *Republic* Glaucon suggests that justice is but a pact among rational egoists. Thomas Hobbes developed this idea to analyse the nature of political power. Given the predominantly self-centred nature of humankind, government is necessary for society. Government's role is to stabilize social cooperation. By exercising enforcement powers, government provides each with the assurance that everyone else will abide by cooperative rules, thereby making it rational for all to cooperate. To fulfil this stabilizing role, Hobbes argued that it is rational for each individual to agree to authorize one person to exercise absolute political power. Neo-Hobbesians eschew absolutism and apply the theory of rational choice to argue that rules of justice, perhaps even all morality, can be construed in terms of a rational bargain among self-interested individuals.

John Locke, working from different premises than Hobbes, appealed to a social compact to argue for a constitutional government with limited powers. All men are born with a natural right to equal freedom, and a natural duty to God to preserve themselves and the rest of mankind. No government is just unless it could be commonly agreed to form a position of equal freedom, where agreement is subject to the moral constraints of natural law. Absolutism is unjust according to this criterion.

Rousseau developed egalitarian features of Locke's view to contend for a democratic constitution. The Social Contract embodies the General Will of society, not the unconstrained private wills of its members. The General Will wills the common good, the good of society and all of its members. Only by bringing our individual wills into accord with the General Will can we achieve civic and moral freedom.

In this century, John Rawls has recast natural rights theories of the social contract to argue for a liberal egalitarian conception of justice. From a position of equality, where each person abstracts from knowledge of their historical situations, it is rational for all to agree on principles of justice that guarantee equal basic freedoms and resources adequate for each person's independence.

T.M. Scanlon, meanwhile, has outlined a rights-based contractualist account of morality. An act is right if it accords with principles that could not be reasonably rejected by persons who are motivated by a desire to justify their actions according to principles that no one else can reasonably reject.

CONVENTIONALISM

How is it known that every number has a successor, that straight lines can intersect each other no more than once, that causes precede their events, and that the electron either went through the slit or it did not? In cases like these it is not easy to find observable evidence, and it is implausible to postulate special modes of intuitive access to the phenomena in question. Yet such theses are relied on in scientific discourse and can hardly be dismissed as meaningless metaphysical excess. In response to this problem the positivists and empiricists (notably Poincaré, Hilbert, Carnap, Reichenbach and Ayer) developed a strategy known as conventionalism. The idea was that certain statements, including fundamental principles of logic, arithmetic and geometry, are asserted as a matter of conventional stipulation, being no more than definitions of some of their constituent terms; consequently they must be true, our commitment to them cannot but be justified, and the facts in virtue of which they are true are simply the facts of our having made those particular decisions about the use of words. This doctrine was a compelling and powerful weapon in the positivist–empiricist arsenal, evolving throughout the 1920s, 1930s and 1940s. But it fell into disfavour under a barrage of serious challenges due mainly to Quine. How are 'conventions' to be identified as such? How could

they possibly provide words with meanings, or have the epistemological import that is claimed for them? How could arbitrary, contingent decisions about the use of words result in the existence of necessary facts? In the absence of satisfactory replies to these objections few philosophers these days believe that conventionalism can settle the semantic, epistemological and metaphysical questions that it was intended to answer. However, certain aspects of the view remain defensible and interesting.

CONWAY, ANNE (*c.*1630–79)

Anne Conway (née Finch) was the most important of the few English women who engaged in philosophy in the seventeenth century. Her reputation derives from one work published after her death, *Principia philosophiae antiquissimae et recentissimae* (1690), which proposes a Neoplatonic system of metaphysics featuring a monistic concept of created substance. The work entails a critique of the dualism of both Descartes and Henry More, as well as of the materialism (as she saw it) of Hobbes and Spinoza. In her concept of the monad and her emphasis on the benevolence of God, Conway's system has some interesting affinities with that of Leibniz.

SARAH HUTTON

COPERNICUS, NICOLAUS (1473–1543)

Copernicus argued that the earth is a planet revolving around the sun, as well as rotating on its own axis. His work marked the culmination of a tradition of mathematical astronomy stretching back beyond Ptolemy, to the Greeks and Babylonians. Though it was associated with methods and assumptions that had been familiar for centuries, it was also revolutionary because of its implications for the relations between humankind and the universe at large.

COSMOLOGICAL ARGUMENT

See God, arguments for the existence of

COSMOLOGY

The term 'cosmology' has three main uses. At its most general, it designates a worldview, for example, the Mayan cosmology. In the early eighteenth century, shortly after the term made its first appearance, Christian Wolff used it to draw a distinction between physics, the empirical study of the material world, and cosmology, the branch of metaphysics dealing with material nature in its most general aspects. This usage remained popular into the twentieth century, especially among Kantian and neo-scholastic philosophers. But recent developments in science that allow the construction of plausible universe models have, effectively, pre-empted the use of the term in order to designate the science that deals with the origins and structure of the physical universe as a whole.

Cosmology may be said to have gone through three major phases, each associated with a single major figure – Aristotle, Newton and Einstein. The ancient Greeks were the first to attempt to give a reasoned account of the cosmos. Aristotle constructed a complex interlocking set of spheres centred on an immovable central earth to account for the motions of the heavenly bodies. Newton formulated a theory of gravitational force that required space and time to be both absolute and infinite. Though the laws of nature could, in principle, be specified, nothing could be said about the origins or overall structure of the cosmos. In 1915, Einstein proposed a general theory of relativity whose field-equations could be satisfied by numerous universe-models. Hubble's discovery of the galactic red shift in 1929 led Lemaître in 1931 to choose from among these alternatives an expanding-universe model, which, though challenged in the 1950s by a rival steady-state theory, became the 'standard' view after the cosmic microwave background radiation it had predicted was observed in 1964. The 'Big Bang' theory has since been modified in one important respect by the addition of an inflationary episode in the first fraction of a second of cosmic expansion. As a 'cosmic' theory, it continues to raise issues of special interest to philosophers.

COUNTERFACTUAL CONDITIONALS

'If bats were deaf, they would hunt during the day.' What you have just read is called a 'counterfactual' conditional; it is an 'If . . . then . . .' statement the components of which are 'counter to fact', in this case counter to the fact that bats hear well and sleep during the day. Among the analyses proposed for such statements, two have been especially prominent. According to the first, a counterfactual asserts that there is a sound argument from the antecedent ('bats are deaf') to the consequent ('bats hunt during the day'). The argument uses certain implicit background conditions and laws of nature as additional premises. A variant of this analysis says that a counterfactual is itself a condensed version of such an argument. The analysis is called 'metalinguistic' because of its reference to linguistic items such as premises and arguments. The second analysis refers instead to possible worlds. (One may think of possible worlds as ways things might have gone.) This analysis says that the example is true just in case bats hunt during the day in the closest possible world(s) where they are deaf

DAVID LEOPOLD

CRIME AND PUNISHMENT

Introduction

An account of how state punishment can be justified requires an account of the state, as having the authority to punish, and of crime, as that which is punished. Crime, as socially proscribed wrongdoing, may be formally censured, and may lead to the payment of compensation to those injured by it – but why should it also attract the kind of 'hard-treatment' punishment which characterizes a system of criminal law? How should we decide which kinds of wrongdoing should count as crimes?

Consequentialists justify punishment by its beneficial effects, notably in preventing crime by deterring, reforming or incapacitating potential criminals. They face the objection that the wholehearted pursuit of such goals would lead to injustice – punishment of those who do not deserve it. Even if that objection is met by imposing non-consequentialist constraints on the system, they also face the objection that a consequentialist system fails to respect criminals as responsible moral agents.

Retributivists hold that punishment must be deserved if it is to be justified, and that the guilty (and only the guilty) deserve punishment. Positive retributivists hold that the guilty should be punished as they deserve, even if this will achieve no consequential good. Negative retributivists hold that only the guilty may be punished, but that they should be punished only if their punishment will be beneficial. The main objection to retributivism is that it fails to explain why the guilty deserve punishment.

Some retributivists have argued that the guilty deserve censure, and that punishment serves to communicate that censure. But why should we use 'hard treatment' such as imprisonment or fines to communicate censure? Does the hard treatment function as a consequentialist deterrent? Or could such punishments serve to reform or educate criminals, thus bringing them to repent their crimes and restore their relationships with those they have wronged?

A theory of justified punishment must be related to our existing penal institutions. It must, in particular, have something to say about sentencing: about what kinds of punishment should be imposed, and about how sentencers should decide on the appropriate severity of punishment. A central issue concerns the role of the principle of proportionality: the demand that the severity of punishment should be proportionate to the seriousness of the crime.

But we must also ask whether our existing penal practices can be justified at all. We must face the abolitionists' argument that punishment should be abolished in favour of social practices which treat 'crimes' not as wrongdoings that must be punished, but as 'conflicts' which must be resolved by a reconciliatory rather than a punitive process.

1 Punishment, the state and the criminal law

Our focus is on punishment imposed by the state for breaches of the criminal law. Punishment can be initially defined as the deliberate infliction of something meant to be burdensome, by an authority, on an alleged offender, for an alleged offence. It needs justification because it involves doing things (depriving people of life, liberty or money) which are normally wrong. Different moral perspectives, however, generate different accounts of why punishment is morally problematic and thus of what could justify it. Is what matters the infliction of pain, for instance; or the apparent coercive infringement of rights which punishment involves?

A justification of state punishment presupposes a normative theory of the state, as having the authority to punish. Different theories of the state generate different conceptions of punishment: a liberal theory, for example, might set more modest aims for state punishment, and subject it to stricter constraints, than would a communitarian theory (see LIBERALISM; COMMUNITY AND COMMUNITARIANISM).

A justification of punishment also requires an account of crime, since it is crimes that are punished. Crime can be minimally defined as socially proscribed wrongdoing, breaching an authoritative social norm. We require an account of the proper character and scope of such norms (and of what it is to be responsible for breaching them, since crime involves a criminal who can be held responsible for it) (see RESPONSIBILITY). But not all breaches of socially (or legally) authoritative norms count as crimes which merit punishment: we must ask what kinds of response are appropriate to different kinds of wrongdoing.

Censure is one proper response to breaches of authoritative norms, and the expression of censure may be a further defining feature of punishment; this distinguishes fines, for instance, from taxes (see §3). But censure can be expressed by formal declarations, or by symbolic punishments which are painful only in virtue of their expressive meaning, whereas criminal punishments typically inflict 'hard treatment' (the loss of liberty, money or life) which is painful independently of its expressive meaning. Why should such hard treatment be an appropriate response to socially proscribed wrongdoing?

Another response to such wrongdoing is the enforced payment of compensation to those harmed by it; this is a central feature of the civil as distinct from the criminal law. But though punishment may involve the payment of compensation, it also inflicts hard treatment that is not directly compensatory (nor do crimes always harm identifiable victims). Why should such punitive hard treatment ever be appropriate, and for what kinds of conduct? Which should count as crimes, rather than merely as civil wrongs?

Some theorists appeal to the 'harm principle' (see LAW AND MORALITY §2): only conduct which harms or endangers others should be criminal. But this provides at most a necessary, not a sufficient, condition for criminalization: not every kind of (even seriously) harmful conduct is a plausible candidate for criminalization. And, apart from the question of whether paternalistic laws, prohibiting conduct that harms only the agent, can ever be justified, we must ask what counts as 'harm'. Can we distinguish harmful from merely offensive conduct? Might we count some conduct as 'harmful' purely because of its moral character (as, for example, a breach of trust or a denial of rights) rather than because of its material effects?

Whether we talk of conduct that harms interests, or that infringes rights, or that flouts community values, we must ask which interests, rights or values should be protected by the criminal rather than the civil law. Crimes are often said to be public, rather than private or individual, wrongs: wrongs not just against some individual who may then claim damages, but against the community or state. That is why while civil cases are brought (and may be dropped) by individual plaintiffs, criminal cases are brought by the state or community, even when they involve an attack on an individual victim. But can we explain crimes as public wrongs, without distorting the way in which many crimes attack individual victims? To say, for instance, that murder and rape should be crimes not because of what they do to their particular victims, but because they threaten public order, seems to deny the significance of the victim's suffering. We might suggest that even crimes against individual victims should count as 'public' wrongs in that the community should identify itself with the victim, counting the victim's wrong as 'ours'. Or we might abandon the idea of crimes as public wrongs (except for those which directly injure the collective rather than any individual, like tax evasion), and portray crimes as attacks on those central rights or interests which the state should protect. Either approach, however, leaves us with the question of which rights or interests should be thus protected, or which wrongs should thus be seen as public wrongs. Or if we say that the criminal law should protect the values which are essential to the identity or existence of the community, we must ask which those values are. (Any account of crime must also explain the distinction between *mala in se*, acts which are wrong independently of any legal rule, and *mala*

prohibita, acts which are wrong only because prohibited. *Mala prohibita*, however, include many offences (notably 'regulatory' offences, such as minor traffic violations) which some think should not count as true 'crimes': they should be dealt with, not by a criminal process which censures and punishes, but by some distinct regulatory procedure.)

Instead of asking directly which kinds of conduct should be criminalized, we might ask what justifies criminal punishment, and found our principles of criminalization on our answer to that question. If the central justifying aim of punishment is deterrence, we can ask which kinds of conduct should be thus deterred; if its proper aim is 'retribution', we can ask which kinds of conduct merit such a retributive response.

2 Consequentialism and retributivism

Penal theory has long been a battleground between consequentialists and retributivists. After a period of consequentialist domination, the 1970s saw a revival in retributivist thought, as part of a wider rights-based reaction against consequentialism in social policy.

Consequentialists justify punishment by its instrumental contribution to certain goods: most obviously, the good of crime-prevention. A penal system is justified if its crime-preventive and other benefits outweigh its costs, and no alternative practice could achieve such goods more cost-effectively. Punishment prevents crime by deterring, incapacitating or reforming potential offenders: by giving them prudential disincentives to crime, by subjecting them to restraints which make it harder for them to break the law, or by so modifying their attitudes that they will obey the law willingly (see BENTHAM, J.; CONSEQUENTIALISM).

It is at most a contingent truth that such effects on potential offenders are efficiently achieved by punishing actual offenders. This generates the familiar objection to any purely consequentialist theory, that it sanctions injustice. A system of deterrent punishment must appear to punish actual offenders: but that leaves open the possibility of framing innocent scapegoats to deter others or to reassure the public. And unless actual offending is the only reliable predictor of the future crimes which reformative or incapacitative measures aim to prevent, such measures might be efficiently (but surely unjustly) inflicted on those who have not yet broken the law but are thought likely to do so. Indeed, since a person's subjection to coercive treatment by the state must depend on the predicted effects of such treatment, rather than on their past conduct, we might wonder whether consequentialists can justify a system of punishment, of measures imposed for a crime, at all.

Some consequentialists do argue that we should replace punishment by other, more efficient methods of dealing with socially dangerous people. Others argue that we should accept the 'injustices' that a strictly consequentialist penal system might perpetrate (noting that we already accept, for instance, the pre-emptive detention of the mentally disordered). Most accept, however, that a justified system of punishment cannot perpetrate the kinds of gross injustice noted above.

Consequentialists might meet this objection by providing a fuller account of the goods to be achieved or protected, and of the methods by which they might practicably be achieved. Thus some argue that individual freedom is an essential good, whose protection precludes the deliberate punishment of those who have not voluntarily broken the law. Others argue that, given the fallibility of human agents, the only safe way to pursue the appropriate goods is to set strict constraints on the penal system: for instance, strictly to forbid the deliberate punishment of an innocent. Such consequentialist defences, however, depend on large empirical claims about the likely effects of penal strategies, which cannot easily be verified. Can the demands of justice to which this objection appeals really be adequately grounded in the contingencies on which this consequentialist argument depends?

Another strategy is to abandon pure consequentialism, and impose non-consequentialist side-constraints of justice on our pursuit of the consequentialist's goals: to insist, for instance, that only those who have voluntarily broken the law may be punished, since responsible agents have a right not to be subjected to such coercive measures unless they voluntarily make themselves liable to them.

One objection to even a side-constrained consequentialist theory concerns the moral standing of those who are punished or threatened with punishment: that a consequentialist system fails to respect its citizens (criminals and non-criminals) as responsible agents. A system of deterrent punishments, Hegel argued, treats all those whom it threatens with punishment like 'dogs': rather than seeking their allegiance to the law by appeal to the moral reasons which justify its demands, it coerces their obedience by threats (see HEGEL, G.W.F. §8). A consequentialist system of reform similarly treats those subjected to it as objects to be remoulded, rather than as responsible agents who must determine their own conduct.

Against such objections, some argue that a side-constrained system of deterrent punishments can respect the moral standing of those it threatens and

punishes; or that 'rehabilitation' and 'reform' need not be improperly manipulative or coercive. But one stimulus to the retributivist revival in the 1970s was the claim that only retributivism respects the moral standing of criminals: their right to receive 'fair and certain punishment', rather than being 'used merely as means' to the deterrence of others, or being subjected to indefinite terms of reformative 'treatment'.

The central retributivist slogan is that (only) the guilty deserve punishment, and deserve punishments proportionate to the seriousness of their crimes. This demand for 'just deserts' may be interpreted negatively, as forbidding the punishment of the innocent (or the excessive punishment of the guilty); or positively, as requiring that the guilty be punished as they deserve. The negative reading makes guilt a necessary, but not sufficient, condition of justified punishment: it suggests a 'mixed' account, which gives punishment a consequentialist aim but subjects our pursuit of that aim to retributivist side-constraints, requiring that punishment be both deserved and consequentially beneficial. The positive reading makes guilt a necessary and sufficient condition of justified punishment: the guilty should be punished because they deserve it, whether or not their punishment achieves any consequential good (see KANT, I. §10).

The central task for any retributivist is to explain this supposed justificatory relation between guilt and punishment: what is it about crime that makes punishment an appropriate response to it? The central objection to all retributivist theories is that they fail to discharge this task: they either fail to explain this notion of penal desert, falling back on unexplained intuition or metaphysical mystery-mongering, or offer covertly consequentialist explanations.

The 'new retributivism' of the 1970s offered various accounts of the idea of penal desert. One was that criminals gained by their crimes an unfair advantage over the law-abiding, since they accepted the benefits of the law-abiding self-restraint of others, but evaded that burden of self-restraint themselves: their punishment removed that unfair advantage, thus restoring the fair balance of benefits and burdens which the law should preserve. One objection to this account is that it distorts the nature of crime: what makes rape punishable as a crime is surely the wrong done to its victim, not the unfair advantage the rapist supposedly takes over all those who obey the law.

Another trend in recent retributivist thought has rather built on the idea of punishment as an expressive or communicative practice.

3 Punishment and communication

Expressive accounts of punishment need not be retributivist: since by expressing censure we can modify wrongdoers' conduct, consequentialists can advocate expressive punishments. But the expressive or communicative aspect of punishment can explain the retributivist's slogan that the guilty deserve punishment: if they have broken a law which justifiably claimed their obedience, they deserve censure; and it is a proper task for the state, speaking on behalf of the community, to communicate that censure to them.

We should talk of communication rather than of expression here. For communication is a process which addresses (as expression need not) another as a rational agent; it captures the idea (central to recent versions of retributivism), that we must address criminals as rational and responsible agents.

But even if criminal wrongdoers should be censured, and hard-treatment punishments of the sort imposed by our penal systems can communicate that censure, we must ask why it should be communicated in this way, rather than by formal declarations or purely symbolic punishments (see §1).

Some suggest that hard treatment is necessary if the censure which wrongdoing merits is to be communicated effectively to the criminal, who might not attend to merely symbolic punishments; or that it may be necessary to 'defeat' the claim to superiority which was implicit in the wrongdoer's crime (but do all crimes make such a claim?). But why, if not for the consequentialist reason that this will make the punishment a more effective deterrent, is effective communication so crucial that we must inflict hard-treatment punishments to achieve it?

Others accept that a communicative retributivism cannot by itself justify the use of hard treatment as the communicative vehicle: it must be justified by a consequentialist concern for deterrence. This need not be the kind of 'mixed' account which portrays retributivist values merely as side-constraints on the consequentialist ends which give the penal system its positive aim. The communication of censure can itself be the central justifying aim of punishment, so that the law addresses the citizen as a responsible moral agent, appealing to the moral reasons which justify its demands and the censure that it imposes on those who flout those demands. But recognizing that, as fallible human beings, we will not always be adequately motivated by such moral reasons for obeying the law, we communicate that censure through hard treatment in order to provide an additional prudential incentive for obedience. On

one version of this account, the hard treatment should provide only a modest prudential supplement which does not replace or drown the law's moral voice: the question then is whether such modest supplements will be effective. On another version, the hard treatment may be harsh enough to provide by itself an effective deterrent; but this will revive the objections noted earlier to a deterrent conception of punishment.

More ambitiously communicative accounts of punishment portray the hard treatment as a mode of moral communication which aims to reform or educate. Punishment aims to bring wrongdoers to understand and to repent their crimes, and thus to reform their future conduct. Hard treatment assists this purpose by helping to bring home to them the meaning and implications of what they have done; it can also, if it is willingly undergone, enable them to express their repentance and thus reconcile themselves with their victims and the community. Such accounts are retributivist, since punishment must be focused on the past crime as an appropriate censuring response to it, but they also give punishment a forward-looking purpose: the offender's reform or rehabilitation, the restoration of the relationships which the crime damaged, the making of symbolic (and perhaps material) reparation to the victim and the community. Such purposes, however, are not to be understood in strictly consequentialist terms, as independent ends to which punishment is a contingent means: they can be achieved only through a punitive process which aims to persuade wrongdoers that they must suffer punishment for what they have done.

We must ask, however, whether hard-treatment punishment could ever be an appropriate vehicle for such a communicative, reformative and penitential endeavour; and whether, even if it could (as it might be in, for instance, a religious community that practises penance), the state should take such a coercive interest in the moral condition of its citizens. This conception of punishment might be at home within a communitarian perspective according to which individuals can find their identity and their good only as members of a community united by shared values and mutual concerns; but it seems incompatible with a liberal insistence on the need to protect individual rights and privacy against intrusive state or community power. Liberals can argue that punishment's primary purpose should be the communication of appropriate censure, but may deny that the state should try, by such coercive means, to secure repentance and reform; in which case hard-treatment punishments could be justified only as prudential deterrents which do not seek to invade the criminal's soul.

4 Penal theory and sentencing

Philosophical discussions of punishment are typically conducted at a level of high abstraction, remote both from the actualities of penal practices and from the pressing concerns of penal practitioners. But we must try to relate them to the real penal world.

One central issue is that of sentencing. What kinds of punishment should be available to the courts (capital punishment; imprisonment; fines; community service; probation)? What makes a particular kind of punishment appropriate, either generally or for a particular crime? How should sentencers determine the severity of punishment to be imposed on particular crimes or criminals?

Discussion of the last question often focuses on the principle of proportionality: the severity of punishment should be proportionate to the seriousness of the crime. Some such principle is integral to any retributivist theory, including communicative theories: for if punishment is to communicate an appropriate degree of censure, its severity must be proportionate to the seriousness of the crime. The application of such a principle requires some way of assessing and comparing the seriousness of different crimes, and the severity of different punishments; and it is not clear either just how, or how precisely, this can be done. Furthermore, while such a principle can help to determine the relative severity of sentences, requiring that more serious crimes be punished more severely, and so on, it is not clear whether it can help to fix absolute levels of punishment.

How important is the principle of proportionality? On some views, it is paramount: the primary aim of sentencing is to do justice by assigning proportionate sentences. This means, in practice, that the available range of punishments must be limited, and that the courts should have only very limited discretion in sentencing. Others argue that the demand for proportionality must be weighed against other relevant principles, such as a principle of penal parsimony which requires courts to impose the lightest acceptable sentence, even if that is lighter than is required for strict proportionality; on this view proportionality might be seen as a limiting principle requiring that criminals be punished no more severely than is proportionate to their crimes.

There is also a tension between the demand for proportionality and any ambitious account of punishment as communication. If punishment is given an educative, reformative or penitential aim, courts should seek punishments which are materially appropriate, rather than just formally proportionate, to the crime and the criminal: punishments which will appropriately address the particular

criminal. But this would require the courts to be given a more flexible and creative discretion in sentencing, to find or construct sentences appropriate to the particular case: a discretion which might undermine demands for strict and formal proportionality.

Here again we face a conflict between a liberal perspective which emphasizes the demands of formal justice, and seeks to protect the citizen against the coercive and discretionary power of the state; and a more ambitious conception of the proper role of the state and the criminal law in seeking the moral good of the citizens.

5 Can punishment be justified?

Any plausible normative theory of punishment will show our existing penal institutions to be radically imperfect. The kind and degree of suffering that they inflict cannot be plausibly portrayed as either consequentially cost-effective or retributively just, or well-suited to the aims of a communicative theory of punishment. Nor is it clear that the preconditions of justified punishment are satisfied in our own societies, especially if punishment is portrayed in retributive or communicative terms: can we truly say that most of those who are convicted by our courts have culpably flouted laws which justifiably claimed their allegiance, or that we (in whose name the law speaks) have the moral standing to censure them?

The radical imperfection of our existing penal institutions raises a serious question for any citizen. Should we accept those existing institutions (while also striving for their reform) as necessary to the prevention of yet greater disorder or injustice; or may we have to recognize that they perpetrate such serious injustice, or cause so much harm, that they cannot be justified at all?

The suggestion that, even if a practice of state punishment could in principle be justified, our existing penal institutions may lack any adequate justification, might seem frivolous: can we honestly argue that they should be abolished? But this is just what is argued by 'abolitionists', many of whom indeed argue that punishment cannot even in principle be justified: we should work not for the reform of our penal institutions, but for their abolition. Such arguments are not often considered in the philosophical literature, which tends to assume that the key issue is not whether, but how, state punishment can be justified; but they present a challenge that must be taken seriously.

Various themes run through abolitionist writings. One concerns the very concept of 'crime' as that which merits a punitive response: we should reconceptualize crimes as 'conflicts' that require resolution rather than punishment. Relatedly, we should 'civilize' our response to crime, favouring a civil law rather than a criminal model: rather than seeking 'retributive' justice by condemning and punishing those judged to have done wrong, we should seek 'restorative' justice by striving to reconcile the conflicting parties and (where necessary) negotiating reparation for whatever harm has been done. These themes are often accompanied by an advocacy of 'informal justice': rather than allowing the state to 'steal' conflicts from the individuals and local communities to whom they properly belong, we should look for informal, participatory modes of conflict-resolution. But punishment (the deliberate infliction of suffering) is never justified: neither as retribution (which is not a proper aim), nor as deterrence (which denies the moral standing of those who are threatened and punished). And while rehabilitative facilities may be offered to those who need and seek them, they can never properly be imposed on citizens.

Against such views it may be argued that some 'conflicts' involve the commission of genuine wrongs which should be condemned; that any morally acceptable 'reconciliation' must involve the recognition and acceptance of guilt by the wrongdoer (these considerations argue in favour of a communicative conception of punishment as censure); and that a society which truly forswore the whole coercive apparatus of criminal justice would be unable to protect itself or its members against seriously destructive wrongs and social disorder. We might imagine a more perfect society in which the kinds of hard-treatment punishment currently imposed would be unjustified, because unnecessary. We may agree that we now punish too much, too harshly, that our penal institutions do not serve the ends that punishment should serve, and that too often they inflict further suffering on those who are already seriously disadvantaged by the political and economic structures from which many of us benefit. Abolitionists forcibly remind us of these points; but this is not to agree that punishment can never be justified.

CRITERIA

The concept of criteria has been interpreted as the central notion in the later Wittgenstein's account of how language functions, in contrast to the realist semantics of the *Tractatus*. According to this later account, a concept possesses a sense in so far as there are conditions that constitute non-inductive evidence for its application in a particular case. This condition on a concept's possessing a sense has been thought to enable Wittgenstein to refute both solipsism and scepticism about other minds. There are powerful objections to this conception of criteria, which have led some philosophers to look for an alternative account of the role of criteria in Wittgenstein's later philosophy.

CRITICAL REALISM

Critical realism is a movement in philosophy and the human sciences starting from Roy Bhaskar's writings. It claims that causal laws state the tendencies of things grounded in their structures, not invariable conjunctions, which are rare outside experiments. Therefore, positivist accounts of science are wrong, but so is the refusal to explain the human world causally. Critical realism holds that there is more to 'what is' than 'what is known', more to powers than their use, and more to society than the individuals composing it. It rejects the widespread view that explanation is always neutral – to explain can be to criticize.

ANDREW COLLIER

CRITICAL THEORY

The term 'critical theory' designates the approach to the study of society developed between 1930 and 1970 by the so-called 'Frankfurt School'. Comprising a group of theorists associated with the Institute for Social Research, the School was founded in Frankfurt, Germany in 1923. The three most important philosophers belonging to it were Max Horkheimer, Theodor Wiesengrund Adorno and Herbert Marcuse.

Horkheimer, Adorno and Marcuse feared that modern Western societies were turning into closed, totalitarian systems in which all individual autonomy was eliminated. In their earliest writings from the 1930s they presented this tendency towards totalitarianism as one result of the capitalist mode of production. In later accounts they give more prominence to the role of science and technology in modern society, and to the concomitant, purely 'instrumental', conception of reason. This conception of reason denies that there can be any such thing as inherently rational ends or goals for human action and asserts that reason is concerned exclusively with the choice of effective instruments or means for attaining arbitrary ends.

'Critical theory' was to be a form of resistance to contemporary society; its basic method was to be that of 'internal' or 'immanent' criticism. Every society, it was claimed, must be seen as making a tacit claim to substantive (and not merely instrumental) rationality; that is, making the claim that it allows its members to lead a good life. This claim gives critical theory a standard for criticism which is internal to the society being criticized. Critical theory demonstrates in what ways contemporary society fails to live up to its own claims. The conception of the good life to which each society makes tacit appeal in legitimizing itself will usually not be fully propositionally explicit, so any critical theory will have to begin by extracting a tacit conception of the good life from the beliefs, cultural artefacts and forms of experience present in the society in question. One of the particular difficulties confronting a critical theory of contemporary society is the disappearance of traditional substantive conceptions of the good life that could serve as a basis for internal criticism, and their replacement with the view that modern society needs no legitimation beyond simple reference to its actual efficient functioning, to its 'instrumental' rationality. The ideology of 'instrumental rationality' thus itself becomes a major target for critical theory.

RAYMOND GEUSS

CROCE, BENEDETTO (1866–1952)

The leading Italian philosopher of his day, Croce presented his philosophy as a humanist alternative to the consolations of religion. A Hegelian idealist, he argued that all human activity was orientated towards either the Beautiful, the True, the Useful or the Good. These ideals were the four aspects of what, following Hegel, he termed spirit or human consciousness. The first two corresponded to the

theoretical dimensions of spirit, namely intuition and logic respectively, the last two to spirit's practical aspects of economic and ethical willing. He contended that the four eternal ideals were 'pure concepts' whose content derived from human thought and action. Spirit or consciousness progressively unfolded through human history as our ideas of beauty, truth, usefulness and morality were steadily reworked and developed.

Croce insisted that his idealism was a form of 'absolute historicism', since it involved the claim that all meaning and value evolved immanently through the historical process. He strenuously denied that spirit could be regarded as some form of transcendent puppet-master that existed apart from the human beings through which it expressed itself. He accused Hegel of making this mistake. He also maintained that Hegel's conception of the dialectic as a synthesis of opposites had paid insufficient attention to the need to retain the distinct moments of spirit. He argued that the Beautiful, the True, the Useful and the Good, though linked, ought never to be confused, and he criticized aestheticism and utilitarianism accordingly.

Croce developed his thesis both in philosophical works devoted to aesthetics, ethics, politics and the philosophy of history, and in detailed historical studies of Italian and European literature, culture, politics and society. Opposition to the Fascist regime led him to identify his philosophy with liberalism on the grounds that it emphasized the creativity and autonomy of the individual. In practical politics, however, he was a conservative.

RICHARD BELLAMY

CRUCIAL EXPERIMENTS

A 'crucial experiment' allegedly establishes the truth of one of a set of competing theories. Francis Bacon held that such experiments are frequent in the empirical sciences and are particularly important for terminating an investigation. These claims were denied by Pierre Duhem, who maintained that crucial experiments are impossible in the physical sciences because they require a complete enumeration of all possible theories to explain a phenomenon – something that cannot be achieved. Despite Duhem, scientists frequently regard certain experiments as crucial in the sense that the experimental result helps make one theory among a set of competitors very probable and the others very improbable, given what is currently known.

PETER ACHINSTEIN

CUDWORTH, RALPH (1617–88)

Ralph Cudworth was the leading philosopher of the group known as the Cambridge Platonists. In his lifetime he published only one work of philosophy, his *True Intellectual System of the Universe* (1678). This was intended as the first of a series of three volumes dealing with the general topic of liberty and necessity. Two further parts of this project were published posthumously, from the papers he left when he died: *A Treatise Concerning Eternal and Immutable Morality* (1731) and *A Treatise of Freewill* (1838).

Cudworth's so-called Cambridge Platonism is broadly Neoplatonic, but he was receptive to other currents of thought, both ancient and modern. In philosophy he was an antideterminist who strove to defend theism in rational terms, and to establish the certainty of knowledge and the existence of unchangeable moral principles in the face of the challenge of Hobbes and Spinoza. He admired and borrowed from Descartes, but also criticized aspects of Cartesianism.

Cudworth's starting point is his fundamental belief in the existence of God, conceived as a fully perfect being, infinitely powerful, wise and good. A major part of his *True Intellectual System* is taken up with the demonstration of the existence of God, largely through *consensus gentium* (universal consent) arguments and the argument from design. The intellect behind his 'intellectual system' is the divine understanding. Mind is antecedent to the world, which is intelligible by virtue of the fact that it bears the stamp of its wise creator. The human mind is capable of knowing the world since it participates in the wisdom of God, whence epistemological certainty derives. The created world is also the best possible world, although not bound by necessity. A central element of Cudworth's philosophy is his defence of the freedom of will – a meaningful system of morals would be impossible without this freedom. Natural justice and morality are founded in the goodness and justice of God rather than in an arbitrary divine will. The principles of virtue and goodness, like the elements of truth, exist independently of human beings. *A Treatise Concerning Eternal and Immutable Morality* contains the most fully worked-out epistemology of any of the Cambridge Platonists and constitutes the most important statement of innate-idea epistemology by any British philosopher of the seventeenth century.

CULTURAL RELATIVISM

See Rationality and cultural relativism

CULTURE

Culture comprises those aspects of human activity which are socially rather than genetically transmitted. Each social group is characterized by its own culture, which informs the thought and activity of its members in myriad ways, perceptible and imperceptible. The notion of culture, as an explanatory concept, gained prominence at the end of the eighteenth century, as a reaction against the Enlightenment's belief in the unity of mankind and universal progress. According to J.G. Herder, each culture is different and has its own systems of meaning and value, and cannot be ranked on any universal scale. Followers of Herder, such as Nietzsche and Spengler, stressed the organic nature of culture and praised cultural particularity against what Spengler called civilization, the world city in which cultural distinctions are eroded. It is difficult, however, to see how Herder and his followers avoid an ultimately self-defeating cultural relativism; the task of those who understand the significance of human culture is to make sense of it without sealing cultures off from one another and making interplay between them impossible.

Over and above the anthropological sense of culture, there is also the sense of culture as that through which a people's highest spiritual and artistic aspirations are articulated. Culture in this sense has been seen by Matthew Arnold and others as a substitute for religion, or as a kind of secular religion. While culture in this sense can certainly inveigh against materialism, it is less clear that it can do this effectively without a basis in religion. Nor is it clear that a rigid distinction between high and low culture is desirable. It is, in fact, only the artistic modernists of the twentieth century who have articulated such a distinction in their work, to the detriment of the high and the low culture of our time.

DAOIST PHILOSOPHY

Early Daoist philosophy has had an incalculable influence on the development of Chinese philosophy and culture. Philosophical Daoism is often called 'Lao–Zhuang' philosophy, referring directly to the two central and most influential texts, the *Daodejing* (or *Laozi*) and the *Zhuangzi*, both of which were composite, probably compiled in the fourth and third centuries BC. Beyond these two texts we might include the syncretic *Huainanzi* (*c.*140 BC) and the *Liezi*, reconstituted around the fourth century AD, as part of the traditional Daoist corpus.

Second in influence only to the Confucian school, the classical Daoist philosophers in many ways have been construed as both a critique on and a complement to the more conservative, regulatory precepts of their Confucian rivals. Daoism has frequently and unfortunately been characterized in terms of passivity, femininity, quietism and spirituality, a doctrine embraced by artists, recluses and religious mystics. Confucianism, by contrast, has been cast in the language of moral precepts, virtues, imperial edicts and regulative methods, a doctrine embodied in and administered by the state official. The injudicious application of this *yin–yang*-like concept to Daoism and Confucianism tends to impoverish our appreciation of the richness and complexity of these two traditions. Used in a heavy-handed way, it obfuscates the fundamental wholeness of both the Confucian and Daoist visions of meaningful human existence by imposing an unwarranted conservatism on classical Confucianism, and an unjustified radicalism on Daoism.

There is a common ground shared by the teachings of classical Confucianism and Daoism in the advocacy of self-cultivation. In general terms, both traditions treat life as an art rather than a science. Both express a 'this-wordly' concern for the concrete details of immediate existence rather than exercising their minds in the service of grand abstractions and ideals. Both acknowledge the uniqueness, importance and primacy of the particular person and the person's contribution to the world, while at the same time stressing the ecological interrelatedness and interdependence of this person with their context.

However, there are also important differences. For the Daoists, the Confucian penchant for reading the 'constant *dao*' myopically as the 'human *dao*' is to experience the world at a level that generates a dichotomy between the human and natural worlds. The argument against the Confucian seems to be that the Confucians do not take the ecological sensitivity far enough, defining self-cultivation in purely human terms. It is the focused concern for the overcoming of discreteness by a spiritual extension and integration in the human world that gives classical Confucianism its socio-political and practical orientation. But from the Daoist perspective, 'overcoming discreteness' is not simply the redefinition of the limits of one's concerns and responsibilities within the confines of the human sphere. The Daoists reject the notion that human experience occurs in a vacuum, and that the whole process of existence can be reduced to human values and purposes.

To the extent that Daoism is prescriptive, it is so not by articulating rules to follow or asserting the existence of some underlying moral principle, but by describing the conduct of an achieved human being – the sage (*shengren*) or the Authentic Person (*zhenren*) – as a recommended object of emulation. The model for this human ideal, in turn, is the orderly, elegant and harmonious processes of nature. Throughout the philosophical Daoist corpus, there is a 'grand' analogy established in the shared vocabulary used to describe the conduct of the achieved human being on the one hand, and the harmony achieved in the mutual accomodations of natural phenomena on the other.

The perceived order is an achievement, not a given. Because *dao* is an emergent, 'bottom-up' order rather than something imposed, the question is: what is the optimal relationship between *de* and

dao, between a particular and its environing conditions? The Daoist response is the self-dispositioning of particulars into relationships which allow the fullest degree of self-disclosure and development. In the Daoist literature, this kind of optimally appropriate action is often described as *wuwei*, 'not acting wilfully', 'acting naturally' or 'non-assertive activity'. *Wuwei*, then, is the negation of that kind of 'making' or 'doing' which requires that a particular sacrifice its own integrity in acting on behalf of something 'other', a negation of that kind of engagement that makes something false to itself. *Wuwei* activity 'characterizes' – that is, produces the character or ethos of – an aesthetically contrived composition. There is no ideal, no closed perfectedness. Ongoing creative achievement itself provides novel possibilities for a richer creativity. *Wuwei* activity is thus fundamentally qualitative: an aesthetic category and, only derivatively, an ethical one. *Wuwei* can be evaluated on aesthetic grounds, allowing that some relationships are more productively *wuwei* than others. Some relationships are more successful than others in maximizing the creative possibilities of oneself in one's environments.

This classical Daoist aesthetic, while articulated in these early texts with inimitable flavour and imagination, was, like most philosophical anarchisms, too intangible and impractical to ever be a serious contender as a formal structure for social and political order. In the early years of the Han dynasty (206 BC–AD 220), there was an attempt in the *Huainanzi* to encourage the Daoist sense of *ethos* by tempering the lofty ideals with a functional practicality. It appropriates a syncretic political framework as a compromise for promoting a kind of practicable Daoism – an anarchism within expedient bounds. While historically the *Huainanzi* fell on deaf ears, it helped to set a pattern for the Daoist contribution to Chinese culture across the sweep of history. Over and over again, in the currency of anecdote and metaphor, identifiably Daoist sensibilities would be expressed through a range of theoretical structures and social grammars, from military strategies, to the dialectical progress of distinctively Chinese schools of Buddhism, to the constantly changing face of poetics and art. It can certainly be argued that the richest models of Confucianism, represented as the convergence of Daoism, Buddhism and Confucianism itself, were an attempt to integrate Confucian concerns with human community with the broader Daoist commitment to an ecologically sensitive humanity.

DARWIN, CHARLES ROBERT (1809–82)

Darwin's *On the Origin of Species* (1859) popularized the theory that all living things have evolved by natural processes from pre-existing forms. This displaced the traditional belief that species were designed by a wise and benevolent God. Darwin showed how many biological phenomena could be explained on the assumption that related species are descended from a common ancestor. Furthermore, he proposed a radical mechanism to explain how the transformations came about, namely, natural selection. This harsh and apparently purposeless mechanism was seen as a major threat to the claim that the universe has a transcendent goal.

Because Darwin openly extended his evolutionism to include the human race, it was necessary to re-examine the foundations of psychology, ethics and social theory. Moral values might be merely the rationalization of instinctive behaviour patterns. Since the process which produced these patterns was driven by struggle, it could be argued that society must inevitably reflect the harshness of nature ('social Darwinism'). Darwin's book has been seen as the trigger for a 'scientific revolution'. It took many decades for both science and Western culture to assimilate the more radical aspects of Darwin's theory. But since the mid-twentieth century Darwin's selection mechanism has become the basis for a highly successful theory of evolution, the human consequences of which are still being debated.

PETER J. BOWLER

DAVIDSON, DONALD (1917–2003)

Donald Davidson's views about the relationship between our conceptions of ourselves as people and as complex physical objects have had significant impact on contemporary discussions of such topics as intention, action, causal explanation and weakness of the will. His collection of essays, *Actions and Events* (1980), contains many seminal contributions in these areas. But perhaps even greater has been the influence of Davidson's philosophy of language, as reflected especially in *Inquiries into Truth and Interpretation* (1984). Among the philosophical issues connected to language on which Davidson has been influential are the nature of truth, the semantic paradoxes, first person authority, indexicals, modality, reference, quotation, metaphor, indeterminacy, convention, realism and the publicity of language.

DE RE/DE DICTO

'*De re*' and '*de dicto*' have been used to label a host of different, albeit interrelated, distinctions. '*De dicto*' means 'of, or concerning, a dictum', that is, something having representative content, such as a sentence, statement or proposition. '*De re*' means 'of, or concerning, a thing'. For example, a *de dicto* belief is a belief that a bearer of representative content is true, while a *de re* belief is a belief concerning some thing, that it has a particular characteristic.

Consider the following example:

> John believes his next-door neighbour is a Buddhist.

This statement is ambiguous. Construed *de dicto*, it is true in the following circumstance. John has never had any contact with his next-door neighbour. Nevertheless, John believes that his next-door neighbour is bound to be a Buddhist. Construed in this *de dicto* fashion, the statement does not attribute to John a belief that is distinctively about a particular individual. In contrast, construed *de re*, it does attribute to John a belief that is about a particular individual. For example, construed *de re*, the statement is true in the following circumstance. John encounters his next-door neighbour, Fred, at a party without realizing that Fred is his next-door neighbour. On the basis of his conversation with Fred, John forms a belief about the individual who is in fact his next-door neighbour to the effect that he is a Buddhist.

ANDRÉ GALLOIS

DEATH

Reflection on death gives rise to a variety of philosophical questions. One of the deepest of these is a question about the nature of death. Typically, philosophers interpret this question as a call for an analysis or definition of the concept of death. Plato, for example, proposed to define death as the separation of soul from body. However, this definition is not acceptable to those who think that there are no souls. It is also unacceptable to anyone who thinks that plants and lower animals have no souls, but can nonetheless die. Others have defined death simply as the cessation of life. This too is problematic, since an organism that goes into suspended animation ceases to live, but may not actually die.

Death is described as 'mysterious', but neither is it clear what this means. Suppose we cannot formulate a satisfactory analysis of the concept of death: in this respect death would be mysterious, but no more so than any other concept that defies analysis. Some have said that what makes death especially mysterious and frightening is the fact that we cannot know what it will be like. Death is typically regarded as a great evil, especially if it strikes someone too soon. However, Epicurus and others argued that death cannot harm those who die, since people go out of existence when they die, and people cannot be harmed at times when they do not exist. Others have countered that the evil of death may lie in the fact that death deprives us of the goods we would have enjoyed if we had lived. On this view, death may be a great evil for a person, even if they cease to exist at the moment of death.

Philosophers have also been concerned with the question of whether people can survive death. This is open to several interpretations, depending on what we understand to be people and what we mean by 'survive'. Traditional materialists take each person to be a purely physical object – a human body. Since human bodies generally continue to exist after death, such materialists presumably must say that we generally survive death. However, such survival would be of little value to the deceased, since the surviving entity is just a lifeless corpse. Dualists take each person to have both a body and a soul. A dualist may maintain that at death the soul separates from the body, thereby continuing to enjoy (or suffer) various experiences after the body has died.

Some who believe in survival think that the eternal life of the soul after bodily death can be a good beyond comparison. But Bernard Williams has argued that eternal life would be profoundly unattractive. If we imagine ourselves perpetually stuck at a given age, we may reasonably fear that eternal life will eventually become rather boring. On the other hand, if we imagine ourselves experiencing an endless sequence of varied 'lives', each disconnected from the others, then it is

questionable whether it will in fact be 'one person' who lives eternally.

Finally, there are questions about death and the meaning of life. Suppose death marks the end of all conscious experience – would our lives be then rendered meaningless? Or would the fact of impending death help us to recognize the value of our lives, and thereby give deeper meaning to life?

DECISION AND GAME THEORY

Decision theory studies individual decision-making in situations in which an individual's choice neither affects nor is affected by other individuals' choices; while game theory studies decision-making in situations where individuals' choices do affect each other. Decision theory asks questions like: what does it mean to choose rationally? How should we make choices when the consequences of our actions are uncertain? Buying insurance and deciding which job to take are examples of the kind of decisions studied by this discipline. Game theory instead applies to all decisions that have a strategic component. The choices of an oligopolist, voting strategies, military tactical problems, deterrence, but also common phenomena such as threatening, promising, conflict and cooperation are its subject matter. In a strategic situation, the goal is not just to choose rationally, but to choose in such a way that a mutual solution is achieved, so that choices 'coordinate' in the right way. The formal methods developed by game theory do not require that the subject making a choice be an intentional agent: coordinated interaction between animals or computers can be successfully modelled as well.

DECISION PROBLEM

See CHURCH'S THEOREM AND THE DECISION PROBLEM

DECONSTRUCTION

Although the term is often used interchangeably (and loosely) alongside others like 'post-structuralism' and 'postmodernism', deconstruction differs from these other movements. Unlike post-structuralism, its sources lie squarely within the tradition of Western philosophical debate about truth, knowledge, logic, language and representation. Where post-structuralism follows the linguist Saussure – or its own version of Saussure – in espousing a radically conventionalist (hence sceptical and relativist) approach to these issues, deconstruction pursues a more complex and critical path, examining the texts of philosophy with an eye to their various blind-spots and contradictions. Where postmodernism blithely declares an end to the typecast 'Enlightenment' or 'modernist' project of truth-seeking rational inquiry, deconstruction preserves the critical spirit of Enlightenment thought while questioning its more dogmatic or complacent habits of belief. It does so primarily through the close reading of philosophical and other texts and by drawing attention to the moments of 'aporia' (unresolved tension or conflict) that tend to be ignored by mainstream exegetes. Yet this is not to say (as its detractors often do) that deconstruction is a kind of all-licensing textualist 'freeplay' which abandons every last standard of interpretive fidelity, rigour or truth. At any rate it is a charge that finds no warrant in the writings of some – Jacques Derrida and Paul de Man chief among them.

CHRISTOPHER NORRIS

DEDEKIND, JULIUS WILHELM RICHARD (1831–1916)

Dedekind is known chiefly, among philosophers, for contributions to the foundations of the arithmetic of the real and the natural numbers. These made available for the first time a systematic and explicit way, starting from very general notions (which Dedekind himself regarded as belonging to logic), to ground the differential and integral calculus without appeal to geometric 'intuition'. This work also forms a pioneering contribution to set theory (further advanced in Dedekind's correspondence with Georg Cantor) and to the general notion of a 'mathematical structure'.

Dedekind's foundational work had a close connection with his advancement of substantive mathematical knowledge, particularly in the theories of algebraic numbers and algebraic functions. His achievements in these fields make him one of the greatest mathematicians of the nineteenth century.

HOWARD STEIN

DEDUCTIVE CLOSURE PRINCIPLE

It seems that one can expand one's body of knowledge by making deductive inferences from propositions one knows. The 'deductive closure principle' captures this idea: if S knows that P, and S correctly deduces Q from P, then S knows that Q. A closely related principle is that knowledge is closed under known logical implication: if S knows that P and S knows that P logically implies Q, then S knows that Q. These principles, if they hold, are guaranteed by general features of the concept of knowledge. They would form part of a logic of knowledge.

An influential argument for scepticism about knowledge of the external world employs the deductive closure principle. The sceptic begins by sketching a logically possible hypothesis, or counter-possibility (for example, that one is a brain in a vat, with computer-induced sense experience) which is logically incompatible with various things one claims to know (such as that one has hands). The proposition that one has hands logically implies the falsity of the sceptical hypothesis. Supposing that one is aware of this implication, the deductive closure principle yields the consequence that if one knows that one has hands, then one knows that one is not a brain in a vat. The sceptic argues that one does not know this: if one were in a vat, then one would have just the sensory evidence one actually has. It follows that one does *not* know that one has hands. Some philosophers have sought to block this argument by denying the deductive closure principle.

DEFINITE DESCRIPTIONS

See Descriptions

DEFINITION

A definition is a statement, declaration or proposal establishing the meaning of an expression. In virtue of the definition, the expression being defined (the 'definiendum') is to acquire the same meaning as the expression in terms of which it is defined (the 'definiens'). For example, 'Man is a rational animal' determines the meaning of the term 'man' by making it synonymous with 'rational animal'. Classical theory maintains that a good definition captures the 'real nature' of what is defined: 'A definition is a phrase signifying a thing's essence' (see Aristotle). Historically, philosophers have come to distinguish these 'real' definitions from 'nominal' definitions that specify the meaning of a linguistic expression rather than signify the essential nature of an object, 'making another understand by Words, what Idea, the term defined stands for' (see Locke).

A further distinction can be drawn between contextual or implicit definitions, on the one hand, and explicit definitions, on the other. Often a definition fixes meaning directly and explicitly: for example, the definition of a proper name might well take the form of an explicit identity statement ('Pegasus = the winged horse') and a definition of a predicate is usually given (or can be re-cast) in the form of an equivalence ('For every x: x is a man if and only if x is a rational animal'). But sometimes the meaning of a term is specified in context, by way of the meaning of larger expressions in which the term occurs. A paradigmatic example of this is Bertrand Russell's analysis of the meaning of the definite article.

G. ALDO ANTONELLI

DEISM

In the popular sense, a deist is someone who believes that God created the world but thereafter has exercised no providential control over what goes on in it. In the proper sense, a deist is someone who affirms a divine creator but denies any divine revelation, holding that human reason alone can give us everything we need to know to live a correct moral and religious life. In this sense of 'deism' some deists held that God exercises providential control over the world and provides for a future state of rewards and punishments, while other deists denied this. However, they all agreed that human reason alone was the basis on which religious questions had to be settled, rejecting the orthodox claim to a special divine revelation of truths that go beyond human reason. Deism flourished in the seventeenth and eighteenth centuries, principally in England, France and America.

WILLIAM L. ROWE

DELEUZE, GILLES (1925–95)

Although grounded in the history of philosophy, Gilles Deleuze's work does not begin with first principles but grasps the philosophical terrain 'in the

middle'. This method overthrows subject–object relations in order to initiate a philosophy of difference and chance that is not derived from static being; a philosophy of the event, not of the signifier-signified; a form of content that consists of a complex of forces that are not separable from their form of expression; the assemblage or body without organs, not the organized ego; time, intensity and duration instead of space; in short, a world in constant motion consisting of becomings and encounters with the 'outside' that such concepts do not grasp.

This radical philosophical project is rendered most clearly in Deleuze (and his collaborator Guattari's concept of the 'rhizome'). The rhizome is a multiplicity without any unity that could fix a subject or object. Any point of the rhizome can and must be connected to any other, though in no fixed order and with no homogeneity. It can break or rupture at any point, yet old connections will start up again or new connections will be made; the rhizome's connections thus have the character of a map, not a structural or generative formation. The rhizome, then, is no model, but a 'line of flight' that opens up the route for encounters and makes philosophy into cartography.

DEMARCATION PROBLEM

The problem of demarcation is to distinguish science from nonscientific disciplines that also purport to make true claims about the world. Various criteria have been proposed by philosophers of science, including that science, unlike 'non-science', (1) is empirical, (2) seeks certainty, (3) proceeds by the use of a scientific method, (4) describes the observable world, not an unobservable one, and (5) is cumulative and progressive.

Philosophers of science offer conflicting view-points concerning these criteria. Some reject one or more completely. For example, while many accept the idea that science is empirical, rationalists reject it, at least for fundamental principles regarding space, matter and motion. Even among empiricists differences emerge, for example between those who advocate that scientific principles must be verifiable and those who deny that this is possible, claiming that falsifiability is all that is required.

Some version of each of these five criteria – considered as goals to be achieved – may be defensible.

PETER ACHINSTEIN

DEMOCRACY

Introduction

Democracy means rule by the people, as contrasted with rule by a special person or group. It is a system of decision making in which everyone who belongs to the political organism making the decision is actually or potentially involved. They all have equal power. There have been competing conceptions about what this involves. On one conception this means that everyone should participate in making the decision themselves, which should emerge from a full discussion. On another conception, it means that everyone should be able to vote between proposals or for representatives who will be entrusted with making the decision; the proposal or representative with most votes wins.

Philosophical problems connected with democracy relate both to its nature and its value. It might seem obvious that democracy has value because it promotes liberty and equality. As compared with, for example, dictatorship, everyone has equal political power and is free from control by a special individual or group. However, at least on the voting conception of democracy, it is the majority who have the control. This means that the minority may not be thought to be treated equally; and they lack liberty in the sense that they are controlled by the majority.

Another objection to democracy is that, by counting everyone's opinions as of equal value, it considers the ignorant as being as important as the knowledgeable, and so does not result in properly informed decisions. However, voting may in certain circumstances be the right way of achieving knowledge. Pooling opinions may lead to better group judgement.

These difficulties with democracy are alleviated by the model which concentrates on mutual discussion rather than people just feeding opinions into a voting mechanism. Opinions should in such circumstances be better formed; and individuals are more obviously equally respected. However, this depends upon them starting from positions of equal power and liberty; rather than being consequences of a democratic procedure, it would seem that equality and liberty are instead prerequisites which are needed in order for it to work properly.

1 What democracy is

Democracy means rule by the people. It is a form of decision making or government whose meaning can be made more precise by contrast with rival forms, such as dictatorship, oligarchy or monarchy. In these rival forms a single person or a select group rules. With democracy this is not so. The people themselves rule and they rule themselves. The same body is both ruler and ruled.

Philosophical accounts of democracy analyse its nature and discuss its value. The two cannot be completely separated. Any account which explains the value of democracy has to provide or presuppose an account of what it is holding to be of value. Conversely, supposedly neutral analyses of the nature of democracy are influenced by values. For example, someone who thinks that democracy is a good thing is liable to analyse it in terms of other features also thought to be good.

The concept of democracy therefore may naturally be thought of as what W.B. Gallie called an essentially contested concept. Such concepts are concepts whose analysis is unresolvable because different analysts read into it their favoured values. For example, before the reunification of Germany, both East and West Germany called themselves democracies. Yet each had very different political systems, one being a Marxist single-party state, the other having economic and political competition with several parties and contested elections. A dispute about which one was really a democracy would be irresolvable.

This account and this example presuppose that democracy is desirable, so there is a competition to lay claim to the honorific title. However, for most of the time since the invention of the concept of democracy it has not been taken to be a term of honour. A kind of democracy did exist in ancient Athens. But, this was a form of government criticized by the leading Greek thinkers of the time, Plato and Aristotle. For most of the time since this early democracy ended, democracy has neither existed nor been thought to be desirable.

Much later, with the creation of the USA, we reach a system which most people today would take to be a paradigmatic example of democracy. Unsurprisingly it was defended by its founding fathers. However, what might surprise us more today is that in one of the most famous of these defences, James Madison was careful not to use 'democracy' as the name for the system he supported. He identifies things called democracies and does not support them; the description he uses instead for the fledgling USA is 'republic'.

What Madison means by a republic is 'a government in which the scheme of representation takes place', and by a democracy 'a society consisting of a small number of citizens, who assemble and administer the government in person' *The Federalist Papers* (1787–8). It might be thought that the central question here is one of size. Commentators writing just before Madison, such as ROUSSEAU (§3) and MONTESQUIEU, held that democracy was only possible in small states; and Madison can be taken to be marking the transition to the modern world, with large states rather than small ones; and a corresponding move from direct democracy to representative government. What is today standardly called democracy is very different from what was standardly so called in the ancient world.

However, size is not the only important distinction here. Individuals in very large modern political units can now be so linked together by modern technology that they can relate to each other much as if they all met together. On the other hand, political decisions by and for small groups are still made in the modern world. It can still be asked of these whether they should be made democratically; and, if so, which sort of democracy is appropriate. So, whatever the size of political unit, questions can arise about the importance of participation or discussion before decisions are made. It can be asked whether democracy should be seen primarily as a mechanism in which people vote for policies or representatives without assembly, participation or discussion. At one extreme (as with Joseph Schumpeter), we could analyse democracy as a competition for votes between professional politicians. At the other extreme, we could analyse democracy as a system in which unanimous decisions are reached after a prolonged discussion which respects the equal autonomy and participation of everyone involved. The former seems more practical, but may not uphold any (other) ideals; the latter seems impressively ideal, but may be ineffective in practice.

It has just been said that voting and representation is at least practical. However, this ignores one prominent problem. This is that the collective view which results from voting may not be related in the way we would wish to the individual views expressed in the votes. In particular this applies if there are three or more options to be arranged in order of preference and there are three or more such individual orderings (see SOCIAL CHOICE). These problems will not be discussed further here; although it should be recognized that many people think that they are an insuperable objection to democratic decision making.

2 The value of democracy

Once we have an idea of democracy, the next question is why, or whether, it is of value. The Greek historians identified the original introduction of democracy with the advance of liberty and equality. Since both liberty and equality are usually thought to be of value, this would seem to be a natural answer to the question. Democracy is of value because it produces liberty and equality. With dictatorship or other forms of special leadership, a particular person or group has more power than others. By contrast, in democracy everyone is equal. Everyone has the same (political) power. So democracy is egalitarian as compared with other forms of government or decision making.

Similarly for liberty. A democracy introduced by the overthrow of a dictator increases political liberty. People have been freed from the control of the dictator. Hence democracy promotes liberty. There are several connected terms here: liberty, freedom, autonomy. However, whichever term is used, this argument seems to work. Consider autonomy. It means, literally, self-rule. Yet this is exactly what happens in democracy, as opposed to other forms of government. The people rule themselves.

However, as always, further inspection makes matters less obvious. Suppose decisions are made by majority vote and someone is in the minority. This person is outvoted and so their wants will not be put into effect. Therefore we can question whether in this (democratic) situation, this person is really autonomous. They are being made to do something which they do not want to do. Hence they are not really autonomous. Similarly for equality. Not everyone is treated equally when majority decisions are adopted, because only the views of some people (the majority) are put into effect. The minority's views are disregarded. Hence they are not treated equally. The winner takes all, and hence winners and losers are not equally treated.

If a community is divided into two parts living in mutual antipathy, this becomes even more obvious. The majority community could, by democratic vote, bear heavily down on the minority community, restricting or removing things it holds to be of fundamental value. In such circumstances the members of the minority community could hardly be said to be at liberty; nor could it be said that they were being equally treated. Hence the phrase, used by Tocqueville in *Democracy in America* (1835) and taken over by J.S. Mill in *On Liberty* (1859), 'the tyranny of the majority'. The initial contrast between democracy and dictatorship has now been left behind. If democracy is really the dictatorship of the majority, then it is not so obvious that democracy promotes freedom and equality.

3 The paradox of democracy

If we examine democracy from the standpoint of the minority, as in the last section, this helps to focus the problem of its value. A democrat thinks that the majority view ought to be enacted. But in voting they also declare their own view about what ought to be enacted. When they are in a minority these diverge and they seem to be caught in a contradiction. There are two incompatible policies, A and not-A. Yet the minority democrat seems to think both that A ought to be enacted (because that is what the majority want) and also that not-A ought to be enacted (because that is their own view). Richard Wollheim (1962) called this the 'paradox of democracy'.

However, if democracy can be given a value, the paradox is resolvable. For what we then have is a simple (and familiar) conflict of values. The democrat's direct view of the matter indicates the value of the course of action for which they voted. But once it is defeated by the majority this rival course of action also possesses value. For it inherits the value of democracy. If, for example, democracy is taken to be an egalitarian procedure, then adopting this rival course of action has egalitarian value.

An example: four of us in a car have to decide to go either to the beach or to the town. There is only one car and we can go to only one place. We agree to decide democratically, by vote. The vote is taken. I vote for the beach, and am outvoted by three to one. The beach is of value to me. This is shown by my vote. However, I am also a democrat. After the vote, the town also has value to me. With the town three people's views are respected; with the beach only one. If I hold that people are of equal value, then I have a reason for the car to go to the town.

4 Democracy and knowledge

In his *Republic* Plato says that 'it is not in the natural course of things for the pilot to beg the crew to take his orders' (*c.*380–367 BC: 489b). The implication is that if we want as a group to go to the right place, it is not sensible to assume that everyone has an equally valid opinion. Instead we should follow the lead of those who know. Hence democracy, which treats everybody's opinions equally, is inefficient as a means of determining the right thing to do (see PLATO §14).

This argument makes several presuppositions and can be resisted by contesting them. Some people can only know more than others about something if

there is indeed something to be known. That is, if there is a truth about the matter independent of people's opinions. But this is precisely what might be contested when the question is what the state should do. This being a matter of value, it might be held that no independent truth, and hence no knowledge, is available. More precisely, it might be thought that a line can be drawn between areas in which knowledge is available, and which, for example, might be handled by a professional, trained civil service; and areas for which no knowledge is obtainable, and which should be left to democratic, untrained, amateur decision. Benjamin Barber, for example, takes the area of politics to be one of action, not truth; and for him democracy takes over in the areas where metaphysics fails, creating its own epistemology.

It should be noticed, however, that an argument for the goodness of democratic decision making cannot simply be made on the basis of a complete scepticism about values. For if no truths about values are available, then no truths about the value of democracy are available either. Hence a valid argument cannot be made from this premise to a conclusion that it is true that democracy is of value.

Conversely, even if it is allowed that there are independent truths about value, it does not directly follow that democracy is an inappropriate way of discovering these truths. For it is quite possible that the truth about what in general the state should do is the kind of truth about which people have a roughly equal capacity. Furthermore, even if people do not have equal capacity, as long as it cannot be told which ones are superior, democracy may still be the appropriate method to use. The Platonic argument assumes that there is a truth about what should happen; that this truth is better known to some people than others; and that it is possible to tell independently of their views which these people are. All these assumptions could be resisted.

If people are of roughly equal capacity (or it cannot be told who is superior) then, as long as everyone is more likely than not to be right, voting and adopting the majority view is an efficient method to use. For the majority decision has a higher probability of being right than any individual decision, as CONDORCET was the first to show. In other words, if I have to make a sequence of decisions about the truth of something and I am in a group each of whose members gets the answer right more often than not, then I do much better systematically following the majority view of the group than my own initial views.

Even if some people clearly have better informed views than others, it still does not follow that democratic decision making is inefficient. For if it is obvious who the experts are, then people with an interest in discovering what is right will generally follow their views. In other words, the same answers will be arrived at as would happen if, as in Plato, the better informed were made dictators. Democracy will not be inferior in discovering of the truth, and will have other advantages.

On the other hand, if it is not obvious who the experts are, then it is indeed the case that the majority view may not follow expert opinion. But, if some people are dictators, it may also be the case that the people who are made dictators are not the ones who are better informed. The dangers of mistake in following majority opinion are matched by the dangers of mistake in making the wrong people the dictators. The Platonic argument only works if the experts can be recognized in advance, for example (as in Plato's *Republic*), because they are educated in a way which ensures that they will have expertise.

5 The use of democracy

Other justifications for democracy are possible. One standard device for justification, for many areas, is utilitarianism (see UTILITARIANISM). Something is justified if it promotes general happiness or utility. It can be asked of a form of government, just like anything else, whether it does tend to promote this. The answer, at least of the classical utilitarians such as BENTHAM and James Mill, is that democracy does.

This argument is expressed most simply in James Mill's *Essay on Government* (1820). He starts with an evaluative and a factual premise. The evaluative premise is utilitarianism. Actions are right in so far as they promote the general happiness. The factual premise is universal self-interest. People seek those things which promote their own interests. The problem is to find the form of government in which both of these premises can be true together, to find the form in which people seeking their own interest will nevertheless do those things which promote the general happiness. It is not difficult to show that representative democracy is the answer. Kings will promote the interest of kings, dictators of dictators, oligarchies of oligarchies. In all cases the interest promoted is that of the ruling group, not that of the people as a whole. However, if the people as a whole are put in charge, they will promote the interests of the people as a whole. Seeking their own interests, they will produce general happiness. Hence both premises are satisfied simultaneously.

It is perhaps unsurprising that the greatest happiness of the greatest number results if the majority (the greatest number) are put in charge. However the answer does depend upon certain presuppositions. It assumes that people act in their

own interests. Even if this is what they generally intend to do (which might be disputed), it does not follow from this that they are successful. For they may not know their interests. For example, it is often held that people discount the future too severely, so they prefer less important immediate interests to more important long-term interests. If this is so, then democratic decisions will lead to too short-term results, which are not even in the interests of those voting.

A related point is that this model takes preferences as they are, without allowing them to be changed by the democratic process. Yet if people are ill informed about what is good for them, it would be better to operate on the preferences before permitting these preferences to be expressed in votes. Democracy treats all votes equally. But people may not be equally informed about their interests. So the result may be that some interests are catered for better than others. Analogously, treating votes equally means that strongly held and weakly held views are considered of equal importance. Yet if the goal is to maximize utility, it may be wrong to follow the weakly held view of a majority rather than the strongly held view of a significant minority. If the utility of getting something is supposed to be roughly proportional to the strength of the desire for it, then it could be that the total of less people multiplied by a greater utility per person is higher than the total of more people multiplied by less utility per person.

6 Other consequences

The idea of utilitarianism as a mere preference-satisfying machine, in which antecedently given preferences are satisfied, has often been criticized. One alternative is to treat the values more objectively. Democracy can then be shown to be good in terms of these independently specified consequences. Such was the approach of J.S. Mill and more recent defenders such as William Nelson. Democracy is justified as a form of education or development; it is taken to be a political system in which individuals are made to think for themselves and are therefore improved. Even if the decisions they make are not the best decisions, it is better for individuals if they try and take part in such decisions.

Another consequence which might justify democracy is the supposed promotion of dynamic economic activity; as opposed to the sluggish effects supposedly emanating from more centralized planning and control. Yet even if democracy does correlate with such beneficial economic circumstances, it is not clear that this by itself can be used as an argument for promoting democracy. Jon Elster identifies the questionable role of such arguments based on indirect effects. For it may be that these other effects only happen if people are attached to democracy for more direct reasons (such as thinking that it is a just form of government). If people were only to support democracy because they thought that it encouraged economic dynamism, then the democracy would not work, and so the economic dynamism would not follow either.

This relates to another familiar problem with starting from antecedent preferences and then taking democracy to be a sort of market mechanism in which these preferences are traded. If people only act through self-interest, trying to get their antecedently given preferences fulfilled, then it is not obvious why they should vote at all. For the advantages of voting will come to them if the others vote and their own vote seems to be merely a cost. At the national government level, it is exceedingly unlikely that any one vote will be decisive. So they would be better off not voting at all.

7 Deliberative democracy

One answer to these problems is to dispense with the idea of democracy being a mechanism for satisfying antecedently given preferences. Instead of taking these as given, democracy should instead be considered a device in which people develop and discover their proper preferences through a process of mutual deliberation. In this account of what has been called ‘deliberative democracy’ (also sometimes ‘discursive democracy’), democracy is centrally a matter of discussion rather than of voting. Recently promoted by such thinkers as J. Cohen, A. Gutmann, or J. Dryzek, it builds on an older idea about public rationality. This is that if people have to develop their view about what is right in public discussion, they are pressed to think about what is right for the group as a whole rather than just themselves So people should participate in a form of decision making in which they share their ideas, discuss together, and, with luck, eventually reach general agreement.

The assumption here is that the arguments naturally used in public discussion are constrained by the desire to reach agreement; and that this in turn requires that people should look as if they are appealing to general principles rather than merely appealing to self-interest. The condition of publicity (that is, of what can be said publicly) imposes constraints. If people think from the general point of view rather than in terms of their own individual interest, the forms of reasoning and the antecedent judgements will be different. Discussion rather than voting therefore becomes the central feature of democracy, and it becomes important that

people can meet and talk together before decisions are made.

These ideas promoting discussion and participation have several presuppositions. They presuppose that people will be better able to work out the truth (about what is good for the group) by working in groups rather than individually. This may be the case if they are all independently motivated by the same desire to discover the truth. It is less obviously the case if there are deep conflicts of interest (such as capital against labour; or country against town; or this world against the next). The supposition is that group discussion leads to more rationality; but in some circumstances group dynamics merely increase and inflame passion, so that people behave badly together in a way that they never would separately.

There are disputes about whether public deliberation is meant to replace voting completely or only to supplement it. A complete replacement is in effect a recommendation of unanimity in decision making. Although this shows full respect for every party involved, it also gives every party a veto and so can block all decision making. A more practical view is to supplement discussion with voting, enabling decisions to be made even when complete agreement cannot be reached. Votes must only be held after discussion, enabling preferences to be modified before they are expressed. There is also the question of whether all decisions should be made by this method or only some fundamental (for example, constitutional) ones. Again work might be given to both deliberation and voting, the public deliberation setting a framework inside which more particular matters might be settled by voting.

There are also problems with respect to the standing of the parties engaged in discussion and, connectedly, the formality of the operation. At the one end is a formal procedure of deliberation, operating according to antecedently adopted rules, and restricted in its membership (so that, for example, only members of a club or country may engage in decision-making discussion of what that club or country should do). At the other end, discussion may happen anywhere, at any time, with anyone who happens to be interested. Informality of operation goes with informality of result, so something nearer the formal end is required for executive decisions of legal entities such as clubs or countries. This illustrates that before discussion may take place as a means of reaching collective decisions, antecedent rules have to be established.

With this the values considered at the start of this discussion – namely, liberty and equality – reappear; only now not as the consequence of democratic activity but as its prerequisites. For if discussion is to reach the right answer, it needs to start with roughly equal power between the discussants. Otherwise discussion will be forced in the interests of the stronger. Hence the idea that democracy needs circumstances of roughly equal wealth (held by Montesquieu and Rousseau). Hence the Marxist criticism that Western liberal democracy works on the fiction of an idealized equality when the real situation is one of greatly unequal economic power. Hence John Rawls' argument that political parties should be paid for by the state to avoid the economically powerful buying votes (see Rawls, J. §2). Hence also the objections of feminist theorists. If men and women are antecedently in a situation of different power, then the supposed equality of democracy will only result in most of the power remaining with the men.

In the more recent promoters of deliberative democracy the same considerations apply. People vary in their deliberative and rhetorical skills. Formal equal permission to speak does not entail equal ability when doing so. Thus, again, some attempt has to be made to set conditions ensuring that the discussion takes place between equal participants. Thus discussion becomes a good, but only if the forum in which the discussion takes place is subject to powerful antecedent control and regulation. Otherwise we return to the bad old world of bargaining between antecedently given preferences from which this optimistic espousal of discussion was meant to save us.

ROSS HARRISON

DEMOCRITUS (mid 5th–4th century BC)

A co-founder with Leucippus of the theory of atomism, The Greek Philosopher Democritus

developed it into a universal system, embracing physics, cosmology, epistemology, psychology and theology. He is also reported to have written on a wide range of topics, including mathematics, ethics, literary criticism and theory of language. His works are lost, except for a substantial number of quotations, mostly on ethics, whose authenticity is disputed. Our knowledge of his principal doctrines depends primarily on Aristotle's critical discussions, and secondarily on reports by historians of philosophy whose work derives from that of Aristotle and his school.

The atomists attempted to reconcile the observable data of plurality, motion and change with Parmenides' denial of the possibility of coming to be or ceasing to be. They postulated an infinite number of unchangeable primary substances, characterized by a minimum range of explanatory properties (shape, size, spatial ordering and orientation within a given arrangement). All observable bodies are aggregates of these basic substances, and what appears as generation and corruption is in fact the formation and dissolution of these aggregates. The basic substances are physically indivisible (whence the term *atomon*, literally 'uncuttable') not merely in fact but in principle: (1) because (as Democritus argued) if it were theoretically possible to divide a material thing *ad infinitum*, the division would reduce the thing to nothing; and (2) because physical division presupposes that the thing divided contains gaps. Atoms are in eternal motion in empty space, the motion caused by an infinite series of prior atomic 'collisions'. (There is reason to believe, however, although the point is disputed, that atoms cannot collide, since they must always be separated by void, however small; hence impact is only apparent, and all action is at a distance.) The void is necessary for motion, but is characterized as 'what-is-not', thus violating the Eleatic principle that what-is-not cannot be.

Democritus seems to have been the first thinker to recognize the observer-dependence of the secondary qualities. He argued from the distinction between appearance and reality to the unreliability of the senses, but it is disputed whether he embraced scepticism, or maintained that theory could make good the deficiency of the senses. He maintained a materialistic account of the mind, explaining thought and perception by the physical impact of images emitted by external objects. This theory gave rise to a naturalistic theology; he held that the gods are a special kind of images, endowed with life and intelligence, intervening in human affairs. The ethical fragments (if genuine) show that he maintained a conservative social philosophy on the basis of a form of enlightened hedonism.

DEMONSTRATIVES AND INDEXICALS

Demonstratives and indexicals are words and phrases whose interpretations are dependent on features of the context in which they are used. For example, the reference of 'I' depends on conditions associated with its use: as you use it, it refers to you; as I use it, it refers to me. In contrast, what 'the inventor of bifocals' refers to does not depend on when or where or by whom it is used. Among indexicals are the words 'here', 'now', 'today', demonstrative pronouns such as 'this', reflexive, possessive and personal pronouns, and compound phrases employing indexicals, such as 'my mother'. C.S. Peirce introduced the term 'indexical' to suggest the idea of pointing (as in 'index finger').

The phenomenon of indexicality figures prominently in recent debates in philosophy. This is because indexicals allow us to express beliefs about our subjective 'place' in the world, beliefs which are the immediate antecedents of action; and some argue that such beliefs are irreducibly indexical. For example, my belief that I am about to be attacked by a bear is distinct from my belief that HD is about to be attacked by a bear, since my having the former belief explains why I act as I do (I flee), whereas my having the latter belief explains nothing unless the explanation continues 'and I believe that I am HD'. It seems impossible to describe the beliefs that prompt my action without the help of 'I'. Similarly, some have argued that indexical-free accounts of the self or of consciousness are necessarily incomplete, so that a purely objective physicalism is impossible. In a different vein, some have argued that our terms for natural substances, kinds and phenomena ('gold', 'water', 'light') are indexical in a way that entails that certain substantive scientific claims – for example, that water is H_2O – are, if true, necessarily true. Thus, reflection on indexicality has yielded some surprising (and controversial) philosophical conclusions.

HARRY DEUTSCH

DENNETT, DANIEL CLEMENT (1942–)

A student of Gilbert Ryle and a connoisseur of cognitive psychology, neuroscience and evolutionary biology, American philosopher Daniel Dennett has urged Rylean views in the philosophy of mind, especially on each title topic of his first book,

Content and Consciousness (1969). He defends a broadly instrumentalist view of propositional attitudes (such as belief and desire) and their intentional contents; like Ryle and the behaviourists, Dennett rejects the idea of beliefs and desires as causally active inner states of people. Construing them in a more purely operational or instrumental fashion, he maintains instead that belief- and desire-ascriptions are merely calculational devices.

Dennett offers a severely deflationary account of consciousness, subjectivity and the phenomenal or qualitative character of sensory states. He maintains that those topics are conceptually posterior to that of propositional-attitude content: the qualitative features of which we are directly conscious in experience are merely the intentional contents of judgments.

DEONTIC LOGIC

Deontic logic is the investigation of the logic of normative concepts, especially obligation ('ought', 'should', 'must'), permission ('may') and prohibition ('ought not', 'forbidden'). Deontic logic differs from normative legal theory and ethics in that it does not attempt to determine which principles hold, nor what obligations exist, for any given system. Rather it seeks to develop a formal language that can adequately represent the normative expressions of natural languages, and to regiment such expressions in a logical system.

The theorems of deontic logic specify relationships both among normative concepts (for example, whatever is obligatory is permissible) and between normative and non-normative concepts (for example, whatever is obligatory is possible). Contemporary research beginning with von Wright treats deontic logic as a branch of modal logic, in so far as (as was noted already by medieval logicians) the logical relations between the obligatory, permissible and forbidden to some extent parallel those between the necessary, possible and impossible (concepts treated in 'alethic' modal logic).

MARVIN BELZER

DEONTOLOGICAL ETHICS

Deontology asserts that there are several distinct duties. Certain kinds of act are intrinsically right and other kinds intrinsically wrong. The rightness or wrongness of any particular act is thus not (or not wholly) determined by the goodness or badness of its consequences. Some ways of treating people, such as killing the innocent, are ruled out, even if the aim is to prevent others doing worse deeds. Many deontologies leave agents considerable scope for developing their own lives in their own way; provided they breach no duty they are free to live as they see fit.

Deontology may not have the theoretical tidiness which many philosophers crave, but has some claim to represent everyday moral thought.

Deontology (the word comes from the Greek *deon* meaning 'one must') typically holds that there are several irreducibly distinct duties, such as promise-keeping and refraining from lying. Some deontologists, such as W.D. Ross (1930), maintain that one of these duties is a duty to do as much good as possible. Most deny that there is such a duty, while conceding that there is a limited duty of benevolence, a duty to do *something* for the less fortunate (see Help and beneficence). All agree, however, that there are occasions when it would be wrong for us to act in a way that would maximize the good, because we would be in breach of some (other) duty. In this respect they are opposed to act-consequentialism (see Consequentialism §§1, 2).

Most deontologies include two important classes of duties. First, there are duties which stem from the social and personal relationships in which we stand to particular people. Parents have duties to children, and children to parents; people have duties in virtue of their jobs and the associations to which they belong; debtors have a duty to repay their creditors, promisors to keep their promises and borrowers to return what has been lent to them (see Family, ethics and the; Friendship; Professional ethics; Promising; Solidarity). Some of these social relationships are ones we enter voluntarily, but many are not. The second kind take the form of general prohibitions or constraints. We should not lie to, cheat, torture or murder *anyone*, even in the pursuit of good aims (see Truthfulness).

Deontology is often described as an agent-relative moral theory, in contrast to act-consequentialism, which is an agent-neutral theory. According to act-consequentialism the identity of the agent makes no difference to what their duty is on any particular occasion; that is determined solely by which of the courses of action open to them will produce the best consequences. In deontology, by contrast, a reference to the agent often plays an ineliminable role in the specification of the duty. This is especially clear in the case of duties which stem from social relationships. I have a duty to help *this* person. Why? Because he or she is *my* friend, or *my* child. I have a duty to pay *my* debts and to keep *my* promises.

Constraints also involve agent-relativity, though in a slightly different way. The duty not to murder

does not take the form of enjoining us to minimize the number of murders. The rule tells me not to commit murder myself even if I could thereby prevent something worse being done, such as two murders being committed. Proponents of deontology think of this as moral integrity; their opponents refer to it disparagingly as 'keeping one's hands clean' (see UTILITARIANISM §5).

Many deontologists hold that our duties, though sometimes very onerous, are quite limited in scope. Provided I am in breach of no duty, I am morally at liberty to devote quite a large part of my time and effort to pursuing my own projects in whatever way I please. This latitude leaves room for acts of supererogation: heroic or saintly acts that clearly go beyond the call of duty, and deserve high praise (see SUPEREROGATION).

There is a sharp division in the deontologist camp over the status of constraints. Some, such as Fried (1978), think of them as absolute: they have no exceptions and may not be breached in any circumstances which we are likely to encounter. Others regard the fact that an act would breach a constraint as providing a weighty objection to it, but one which could be overcome if there were a sufficiently pressing duty on the other side. Conflicts between two duties which are not absolute must be settled by determining which duty is the more pressing in the circumstances.

Deontology gains much of its appeal from the fact that it seems to capture the essential outlines of our everyday moral thinking, but it is open to several objections. First, its claim that there is a plurality of distinct duties runs counter to the theoretician's search for simplicity. The deontologist will reply, of course, that a theory must do justice to the complexity of the phenomena. Second, many deontologists further defy the supposed canons of good theorizing by denying that there is any overarching explanation of why there are the duties there are; they record our conviction that there are such duties without seeking to justify them. Others, usually inspired by Kant, do attempt such an explanation based on some broader precept, such as respect for persons (see KANT, I. §§9–11; KANTIAN ETHICS). Third, those who hold that some kinds of action, such as lying, are absolutely prohibited have to provide clear and detailed criteria for determining the boundary between lying and some supposedly less nefarious activity, such as 'being economical with the truth'. Such casuistry can appear both excessively legalistic and incompatible with the spirit of morality. Fourth, deontology provides no procedure to settle conflicts of duty (though some might think that an advantage). Finally, from a consequentialist perspective, the notion of a constraint seems perverse. If what is wrong with murder is that it is a bad thing, how can it be rational to forbid an agent to commit one murder in order to prevent two? If deontology is to answer this challenge, it must show how it can be that one's duty does not rest (wholly) on the goodness or badness of the results of acting in that way.

DEPICTION

How do pictures work? How are they able to represent what they do? A picture of a goat, for example, is a flat surface covered with marks, yet it depicts a goat, chewing straw, while standing on a hillock. The puzzle of depiction is to understand how the flat marks can do this.

Language poses a similar problem. A written description of a goat will also be a collection of marks on a flat surface, which none the less represent that animal. In the case of language the solution clearly has something to do with the arbitrary way we use those marks. The word 'leg', for example, is applied to legs, but any other mark would do as well, providing we all use it in the same way. In the case of pictures, however, something different seems to be going on. There is not the same freedom in producing a picture of a goat on a hillock chewing straw – the surface must be marked in the *right* way, a way we are not free to choose. So what is the right way?

A helpful thought is that the surface must be marked so as to let us experience it in a special way. With the description, we merely need to know what the words it contains are used to stand for. With the picture, we must instead be able to *see* a goat in it. However, although this does seem right, it is difficult to make clear. After all, we do not see a goat in the same way that we see a horse in a view from a window. For one thing, there is no goat there to be seen. For another, it is not even true that looking at the picture is like looking at a goat. It is partly because of the differences that, as we look at

the picture, we are always aware that it is merely a collection of marks on a flat surface. So what is this special experience, seeing a goat in the picture? This is the question that a philosophical account of depiction must try to answer.

R.D. HOPKINS

DERRIDA, JACQUES (1930–2004)

Jacques Derrida was a prolific French philosopher born in Algeria. His work can be understood in terms of his argument that it is necessary to interrogate the Western philosophical tradition from the standpoint of 'deconstruction'. As an attempt to approach that which remains unthought in this tradition, deconstruction is concerned with the category of the 'wholly other'.

Derrida called into question the 'metaphysics of presence', a valuing of truth as self-identical immediacy which has been sustained by traditional attempts to demonstrate the ontological priority and superiority of speech over writing. Arguing that the distinction between speech and writing can be sustained only by way of a violent exclusion of otherness, Derrida attempted to develop a radically different conception of language, one that would begin from the irreducibility of difference to identity and that would issue in a correspondingly different conception of ethical and political responsibility.

ANDREW CUTROFELLO

DESCARTES, RENÉ (1596–1650)

Introduction

René Descartes, often called the father of modern philosophy, attempted to break with the philosophical traditions of his day and start philosophy anew. Rejecting the Aristotelian philosophy of the schools, the authority of tradition and the authority of the senses, he built a philosophical system that included a method of inquiry, a metaphysics, a mechanistic physics and biology, and an account of human psychology intended to ground an ethics. Descartes was also important as one of the founders of the new analytic geometry, which combines geometry and algebra, and whose certainty provided a kind of model for the rest of his philosophy.

After an education in the scholastic and humanistic traditions, Descartes' earliest work was mostly in mathematics and mathematical physics, in which his most important achievements were his analytical geometry and his discovery of the law of refraction in optics. In this early period he also wrote his unfinished treatise on method, the *Rules for the Direction of the Mind*, which set out a procedure for investigating nature, based on the reduction of complex problems to simpler ones solvable by direct intuition. From these intuitively established foundations, Descartes tried to show how one could then attain the solution of the problems originally posed.

Descartes abandoned these methodological studies by 1628 or 1629, turning first to metaphysics, and soon afterwards to an orderly exposition of his physics and biology in *The World*. But this work was overtly Copernican in its cosmology, and when Galileo was condemned in 1633, Descartes withdrew *The World* from publication; it appeared only after his death.

Descartes' mature philosophy began to appear in 1637 with the publication of a single volume containing the *Geometry*, *Dioptrics* and *Meteors*, three essays in which he presented some of his most notable scientific results, preceded by the *Discourse on the Method*, a semi-autobiographical introduction that outlined his approach to philosophy and the full system into which the specific results fit. In the years following, he published a series of writings in which he set out his system in a more orderly way, beginning with its metaphysical foundations in the *Meditations* (1641), adding his physics in the *Principles of Philosophy* (1644), and offering a sketch of the psychology and moral philosophy in the *Passions of the Soul* (1649).

In our youth, Descartes held, we acquire many prejudices which interfere with the proper use of our reason. Consequently, later we must reject everything we believe and start anew. Hence the *Meditations* begins with a series of arguments intended to cast doubt upon everything formerly believed, and culminating in the hypothesis of an all-deceiving evil genius, a device to keep former beliefs from returning. The rebuilding of the world begins with the discovery of the self through the 'Cogito Argument' ('I am thinking, therefore I exist') – a self known only as a thinking thing, and known independently of the senses. Within this thinking self, Descartes discovers an idea of God, an idea of something so perfect that it could not have been caused in us by anything with less perfection than God Himself. From this he concluded that God must exist which, in turn, guarantees that reason can be trusted. Since we are made in such a way that we cannot help holding certain beliefs (the so-called 'clear and distinct' perceptions), God

would be a deceiver, and thus imperfect, if such beliefs were wrong; any mistakes must be due to our own misuse of reason. This is Descartes' famous epistemological principle of clear and distinct perception. This central argument in Descartes' philosophy, however, is threatened with circularity – the Cartesian Circle – since the arguments that establish the trustworthiness of reason (the Cogito Argument and the argument for the existence of God) themselves seem to depend on the trustworthiness of reason.

Also central to Descartes' metaphysics was the distinction between mind and body. Since the clear and distinct ideas of mind and body are entirely separate, God can create them apart from one another. Therefore, they are distinct substances. The mind is a substance whose essence is thought alone, and hence exists entirely outside geometric categories, including place. Body is a substance whose essence is extension alone, a geometric object without even sensory qualities like colour or taste, which exist only in the perceiving mind. We know that such bodies exist as the causes of sensation: God has given us a great propensity to believe that our sensations come to us from external bodies, and no means to correct that propensity; hence, he would be a deceiver if we were mistaken. But Descartes also held that the mind and body are closely united with one another; sensation and other feelings, such as hunger and pain, arise from this union. Sensations cannot inform us about the real nature of things, but they can be reliable as sources of knowledge useful to maintaining the mind and body unity. While many of Descartes' contemporaries found it difficult to understand how mind and body can relate to one another, Descartes took it as a simple fact of experience that they do. His account of the passions is an account of how this connection leads us to feelings like wonder, love, hatred, desire, joy and sadness, from which all other passions derive. Understanding these passions helps us to control them, which was a central aim of morality for Descartes.

Descartes' account of body as extended substance led to a physics as well. Because to be extended is to be a body, there can be no empty space. Furthermore, since all body is of the same nature, all differences between bodies are to be explained in terms of the size, shape and motion of their component parts, and in terms of the laws of motion that they obey. Descartes attempted to derive these laws from the way in which God, in his constancy, conserves the world at every moment. In these mechanistic terms, Descartes attempted to explain a wide variety of features of the world, from the formation of planetary systems out of an initial chaos, to magnetism, to the vital functions of animals, which he considered to be mere machines.

Descartes never finished working out his ambitious programme in full detail. Though he published the metaphysics and the general portion of his physics, the physical explanation of specific phenomena, especially biological, remained unfinished, as did his moral theory. Despite this, however, Descartes' programme had an enormous influence on the philosophy that followed, both within the substantial group that identified themselves as his followers, and outside.

1 Life

René Descartes was born on 31 March 1596 in the Touraine region of France, in the town of La Haye, later renamed Descartes in his honour. In 1606 or 1607 he was sent to the Collège Royal de La Flèche, run by the Jesuit order. Here he received an education that combined elements of earlier Aristotelian scholasticism with the new humanistic emphasis on the study of language and literature. But the core of the collegiate curriculum was the study of Aristotelian logic, metaphysics, physics and ethics. Descartes left La Flèche in 1614 or 1615, and went to the University of Poitiers, where he received his *baccalauréat* and his *licence en droit* in late 1616. In Part I of the *Discours de la méthode* (*Discourse on the Method*) (1637), he discusses his education in some detail, explaining why he found it increasingly unsatisfactory. In the end, he reports, he left school, rejecting much of what he had been taught there. He chose the life of the military engineer, and set out across Europe to learn his trade, following the armies and the wars. On 10 November 1618, in the course of his travels, he met Isaac Beeckman. An enthusiastic scientific amateur since his early twenties, Beeckman introduced Descartes to some of the new currents in science, the newly revived atomist ideas, and the attempt to combine mathematics and physics (see ATOMISM,

ANCIENT). Despite the fact that they only spent a few months together, Beeckman put Descartes on the path that led to his life's work. A number of discussions between them are preserved in Beeckman's extensive notebooks (1604–34), which still survive, and include problems Beeckman set for Descartes, as well as Descartes' solutions. It was for Beeckman that Descartes wrote his first surviving work, the *Compendium musicum*, a tract on music theory, then considered a branch of what was called mixed mathematics, along with other disciplines such as mathematical astronomy and geometric optics. Exactly a year after first meeting Beeckman, this new path was confirmed for Descartes in a series of three dreams that he interpreted as a call to settle down to his work as a mathematician and philosopher.

During the 1620s, Descartes worked on a number of projects including optics and the mathematics that was eventually to become his analytic geometry. In optics, he discovered the law of refraction – the mathematical law that relates the angle of incidence of a ray of light on a refractive medium, with the angle of refraction. Though some claim that Descartes learned this law from Willebrod Snel, after whom the law is now named, it is generally thought that Descartes discovered it independently. In his mathematical programme, he showed how algebra could be used to solve geometric problems, and how geometric constructions could be used to solve algebraic problems.

Descartes' most extensive writing from this period is the *Regulae ad directionem ingenii* (*Rules for the Direction of the Mind*), a treatise on method that he worked on between 1619 or 1620 and 1628, when he abandoned it incomplete. He continued to travel extensively throughout Europe, returning to Paris in 1625, where he was to stay until spring 1629. In Paris, Descartes became closely associated with Marin Mersenne who later became a central figure in the dissemination of the new philosophy and science in Europe, the organizer of a kind of scientific academy and the centre of a circle of correspondents, as well as Descartes' intellectual patron. Through his voluminous correspondence with Mersenne, Descartes remained connected to all the intellectual currents in Europe, wherever he was to live in later years. An important event in this period took place at a gathering at the home of the Papal Nuncio in Paris in 1627 or 1628, where Descartes, responding to an alchemical lecture by one M. Chandoux, took the occasion to present his own ideas, including his 'fine rule, or natural method' and the principles on which his own philosophy was based (letter to Villebressieu, summer 1631; Descartes 1984–91 vol. 3: 32). This attracted the attention of Cardinal Bérule who, in a private meeting, urged Descartes to develop his philosophy.

In spring 1629 Descartes left Paris and moved to the Low Countries, where he set his methodological writing aside and began his philosophy in earnest. The winter of 1629–30 was largely occupied with the composition of a metaphysical treatise, which, as we shall later see, represents the foundations of his philosophy. The treatise is now lost, but Descartes told Mersenne that it had tried to 'prove the existence of God and of our souls when they are separated from the body, from which follows their immortality' (letter to Mersenne, 25 November 1630; Descartes 1984–91 vol. 3: 29). This was followed by the drafting of *Le Monde* (*The World*), Descartes' mechanist physics and physiology, a book intended for publication. In the first part, also called the *Traité de la lumière* (*Treatise on Light*), Descartes begins with a general account of the distinction between a sensation and the motion of tiny particles of different sizes and shapes that is its cause, followed by an account of the foundations of the laws of nature. After then positing an initial chaos of particles in motion (not *our* cosmos, but one made by God in some unused corner of the world), Descartes argues that by means of the laws of nature alone, this cosmos will sort itself into planetary systems, central suns around which swirl vortices of subtle matter which carry planets with them. He concludes the *Traité de la lumière* with an account of important terrestrial phenomena, including gravity, the tides and light, showing how much like our cosmos this imaginary mechanist cosmos will appear. The second part, the *Traité de l'homme* (*Treatise on Man*), begins abruptly by positing that God made a body that looks exactly like ours, but which is merely a machine. Presumably missing – or never written – is a transition between the two treatises that shows how by the laws of nature alone this human body could arise in our world. (This part of the argument is noted in Part V of the later *Discourse on the Method*.) In the text that we now have, Descartes then went on to argue that all phenomena that pertain to life (thought aside) can arise in this body in a purely mechanical way, including nutrition and digestion, the circulation of blood, the movement of the muscles and the transmission of sensory information to the brain.

By 1633 Descartes had in hand a relatively complete version of his philosophy, from method, to metaphysics, to physics and biology. But in late 1633, he heard of the condemnation of Galileo's Copernicanism in Rome, and cautiously decided not to publish his *World*, which was evidently Copernican (see GALILEO, GALILEI). Indeed, he first decided never to publish anything at all. But the

despair did not last. Between 1634 and 1636, Descartes collected some of the material he had been working on, and prepared three essays for publication, the *Géométrie*, the *Météors* and the *Dioptrique*. These scientific essays were preceded by a general introduction, the *Discours de la méthode pour bien conduir sa raison et chercher la vérité dans les sciences* (*Discourse on the Method for Properly Conducting Reason and Searching for Truth in the Sciences*). The *Discourse* presents itself as autobiography, an account of the path the young author (the book was published anonymously) followed in his discoveries, including a summary of his method (Part II), of his early metaphysical speculations (Part IV) and of the programme of *The World* (Part V). In the scientific essays, Descartes presented some of his most striking results, hiding the foundational elements (such as his apparent Copernicanism and his rejection of scholastic form and matter) that would be most controversial.

While not uncontroversial, the *Discourse* and *Essays* were very successful, and induced Descartes to continue his programme for publishing his philosophy. The next work to appear was the *Meditationes* (*Meditations*) of 1641, which included an extensive selection of objections to the *Meditations* from various scholars in learned Europe, including HOBBES, GASSENDI, ARNAULD, and Mersenne himself, along with Descartes' responses, a total of seven sets in all. This was followed in 1644 by the publication of the *Principia Philosophiae* (*Principles of Philosophy*) in which, after a review of his metaphysics, Descartes gives an exposition of his physics adapted and expanded from *The World*. French translations of the *Meditations* and the *Principles* done by others, but with important variants from the original Latin (presumably introduced by Descartes himself), appeared in 1647.

By the late 1630s, Descartes' work had entered the Dutch universities, and was taught at the University of Utrecht by Henricus Reneri and, following him, by Henricus Regius. Descartes' un-Aristotelian views called down the wrath of Gisbertus Voëtius, who started a pamphlet war against Descartes and Regius that raged for some time. Descartes supported Regius, and gave him advice as to how to respond and contain the affair. Eventually, however, Descartes broke with him when Regius wrote and in 1646 published his *Fundamenta physices*, about which Descartes had severe reservations. Regius responded with a broadsheet, a kind of summary of his main theses, emphasizing their differences. Descartes, in turn, responded in 1648 with the *Notae in programma quoddam* (*Comments on a Certain Broadsheet*). There was a similar incident in Leiden, where Descartes had disciples (François du Ban, Adriaan Heereboord) as well as an influential enemy (Revius).

In the late 1640s Descartes was working on drafting and publishing more of his philosophy. Two additional parts of the *Principles* were planned, extending the work to cover elements of human biology. While notes remain in the form of an incomplete treatise on the human body (*La description du corps humain – Description of the Human Body*) and on the foetus (*Prima cogitationes circa generationem animalium – First Thoughts on the Generation of Animals*), the larger work was never finished. There are also important works concerning morals and moral psychology dating from these years. Some of this material is found in the letters to the Princess Elisabeth of Bohemia, with whom he had a long and important correspondence, starting in 1643. Descartes' account of the passions is found in the last work he published in his lifetime, the short *Passions de l'âme* – (*Passions of the Soul*), which appeared in 1649.

With the exception of a few short trips to Paris in 1644, 1647 and 1648, Descartes remained in the Low Countries until October 1649, when he was lured to Stockholm to be a member of the court of Queen Christina. There he fell ill in early 1650, and died on 11 February of that year.

2 The programme

Descartes' thought developed and changed over the years. But even so, there are a number of threads that run through it. Like most of his lettered contemporaries, Descartes was educated in a scholastic tradition that attempted to combine Christian doctrine with the philosophy of Aristotle. Indeed, at La Flèche, where he first learned philosophy, Aristotle as interpreted by Aquinas was at the centre of the curriculum. What he learned was an interconnected system of philosophy, including logic, physics, cosmology, metaphysics, morals and theology.

On his own account, Descartes rejected the Aristotelian philosophy as soon as he left school. From the notes Beeckman took on their conversations, it is probable that what dissatisfied him most in what he had been taught was natural philosophy. For an Aristotelian, the understanding of the natural world was grounded in a conception of body as composed of matter and form. Matter was that which remained constant even during the generation and corruption of bodies of different kinds, and that which all bodies of all sorts have in common; form was that which was responsible for the characteristic properties of particular sorts of bodies. For example, form was to explain why earth falls and tends to be cold, and why fire rises and tends to be hot. In contrast, though he came to reject Beeckman's rather strict atomism, Descartes seems

to have been attracted to the kind of mechanistic view of the world that his mentor espoused. Descartes held from then on that the manifest properties of bodies must be explained in terms of the size, shape and motion of the tiny parts that make them up, and rejected the appeal to innate tendencies to behaviour that lay at the foundation of the Aristotelian view (see ARISTOTLE §10).

But even though he rejected much of the philosophy of the schools, there was one element that remained with him: like his teachers at La Flèche, Descartes always held that knowledge has a kind of systematic coherence. In Rule 1 of the *Rules* Descartes wrote that 'everything is so interconnected that it is far easier to learn all things together than it is to separate one from the others . . . All [sciences are] connected with one another and depend upon one another'. Later, when he read Galileo's *Two New Sciences* (1638), Descartes dismissed the Italian scientist because his work lacked that kind of coherence (letter to Mersenne, 11 October 1638; Descartes 1984–91 vol. 3: 124–8). His own project was to build his own interconnected system of knowledge, a system comprising an account of knowledge, a metaphysics, a physics and other sciences. This ambition is summarized in one of his last writings, the Preface to the French edition of the *Principles*, where he wrote that 'all philosophy is like a tree, whose roots are metaphysics, whose trunk is physics, and whose branches, which grow from this trunk, are all of the other sciences, which reduce to three principle sciences, namely medicine, mechanics, and morals'. In this way, Descartes saw himself as reconstituting the Aristotelian–Christian synthesis of the scholastics, grounded not in a natural philosophy of matter and form, but in a mechanist conception of body, where everything is to be explained in terms of size, shape and motion.

Certain important features of the Cartesian programme are worth special mention. The Aristotelian–Christian synthesis is founded in a variety of kinds of authority: the authority of the senses, the authority of ancient texts and the authority of his teachers. Descartes wanted to ground his thought in himself alone, and in the reason that God gave him. Since, Descartes claimed, reason gives us genuine certainty, this means that true knowledge is certain. In Rule 3 of the *Rules* he wrote that 'concerning things proposed, one ought to seek not what others have thought, nor what we conjecture, but what we can clearly and evidently intuit or deduce with certainty; for in no other way is knowledge acquired'. The rejection of the authority of the senses, texts and teachers shaped Descartes' thought in fundamental ways. Because of it, his philosophical system began with the Cogito Argument, which establishes the self as the starting-place of knowledge. Moreover, his two most influential works, the *Discourse* and the *Meditations*, were written in the first person so as to *show* the reader how Descartes did or might have come to his own state of knowledge and certainty, rather than *telling* readers what they are to believe, and thus setting himself up as an authority in his own right. Despite his rejection of authority, however, Descartes always claimed to submit himself to the authority of the Church on doctrinal matters, separating the domain of revealed theology from that of philosophy.

Another important feature of Descartes' tree of knowledge was its hierarchical organization. Throughout his career he held firmly to the notion that the interconnected body of knowledge that he sought to build has a particular order. Knowledge, for Descartes, begins in metaphysics, and metaphysics begins with the self. From the self we arrive at God, and from God we arrive at the full knowledge of mind and body. This, in turn, grounds the knowledge of physics, in which the general truths of physics (the nature of body as extension, the denial of the vacuum, the laws of nature) ground more particular truths about the physical world. Physics, in turn, grounds the applied sciences of medicine (the science of the human body), mechanics (the science of machines) and morals (the science of the embodied mind).

3 Method

Before beginning an account of the individual parts of Descartes' tree of knowledge, it is necessary to discuss his method. Method was the focus of his earliest philosophical writing, the *Rules*, and appeared prominently in his first published writing, the *Discourse on the Method*. But what exactly that method was is somewhat obscure.

In the second part of the *Discourse*, the method is presented as having four rules: (1) 'never to accept anything as true if I did not have evident knowledge of its truth: that is, carefully to avoid precipitate conclusions and preconceptions'; (2) 'to divide each of the difficulties I examined into as many parts as possible'; (3) 'to direct my thoughts in an orderly manner, by beginning with the simplest and most easily known objects in order to ascend little by little . . . to knowledge of the most complex'; and (4) 'throughout to make enumerations so complete and reviews so comprehensive, that I could be sure of leaving nothing out'. Given the general nature and apparent obviousness of these rules, it is not surprising that many of Descartes' contemporaries suspected him of hiding his *real* method from the public.

But Descartes' account of the method in the *Rules* is somewhat fuller. In Rule 5 he says: 'We

shall be following this method exactly if we first reduce complicated and obscure propositions step by step to simpler ones, and then, starting with the intuition of the simplest ones of all, try to ascend through the same steps to a knowledge of all the rest'. This method is illustrated with an example in Rule 8. There Descartes considers the problem of the anaclastic line, the shape of a lens which will focus parallel lines to a single point. The first step in the solution of the problem, Descartes claims, is to see that 'the determination of this line depends on the ratio of the angles of refraction to the angles of incidence'. This, in turn, depends on 'the changes in these angles brought about by differences in the media'. But 'these changes depend on the manner in which a ray passes through the entire transparent body, and knowledge of this process presupposes also a knowledge of the nature of the action of light'. Finally, Descartes claims that this last knowledge rests on our knowledge of 'what a natural power in general is'. This last question can, presumably, be answered by intuition alone, that is, a purely rational apprehension of the truth of a proposition that has absolute certainty. Once we know what the nature of a natural power is, we can, Descartes thought, answer one by one all the other questions raised, and eventually answer the question originally posed, and determine the shape of the lens with the required properties. These successive answers are to be connected deductively (in a way outlined in the *Rules*) with the first intuition, so that successive answers follow intuitively from the first intuition.

The example of the anaclastic line suggests that Descartes' method proceeds as follows. One starts with a particular question, q_1. The reductive moment in the method then proceeds by asking what we have to know in order to answer the question originally posed. This leads us from q_1 to another question, q_2, whose answer is presupposed in order for us to be able to answer q_1; it is in this sense that q_1 is said to be reduced to q_2. This reductive process continues until we reach a question whose answer we are capable of knowing through intuition, say q_n. At that point, we begin what might be called the constructive moment of the method, and successively answer the questions we have posed for ourselves, using the answer to q_n to answer q_{n-1}, the answer to q_{n-1} to answer q_{n-2}, and so on until we arrive at q_1, the question originally posed, and answer that.

Understood in this way, the method has some very interesting properties. First, it results in knowledge that is completely certain. When we follow this method, the answer to the question originally posed is grounded in an intuition; the answers to the successive questions in the series are to be answered by deducing propositions from propositions that have been intuitively grasped as well. Second, the method imposes a certain structure on knowledge. As we follow the series of questions that constitute the reductive step of the method, we proceed from more specific questions to more general, from the shape of a particular lens to the law of refraction, and ultimately to the nature of a natural power. The answers that are provided in the constructive stage follow the opposite path, from the metaphysically more general and more basic to the more specific.

The *Rules* was written over a long period of time, and there are numerous strata of composition evident in the work as it survives. In a passage from Rule 8 that is probably in one of the last strata of composition, Descartes raises a problem for the method itself to confront, indeed the *first* problem that it should confront: 'The most useful inquiry we can make at this stage is to ask: What is human knowledge and what is its scope? ... This is a task which everyone with the slightest love of truth ought to undertake at least once in life, since the true instruments of knowledge and the entire method are involved in the investigation of the problem'. While it is not entirely clear what Descartes had in mind here, it is not implausible to interpret him as raising the problem of the justification of intuition itself, the epistemological foundation of the method. In framing the method in the *Rules*, Descartes takes for granted that he has a faculty, intuition, by which he is capable of grasping truth in some immediate way, and what he knows by intuition is worthy of trust. But why *should* we trust intuition? This, in essence, is one of the central questions in the *Meditations*, where Descartes argues that whatever we perceive clearly and distinctly is true.

Method was a central concern of Descartes' earlier writings, in both the *Rules* and the *Discourse*. In later writings it seemed to play little explicit role in his thought, but the hierarchical structure of knowledge with which the method is closely connected – the idea that knowledge is grounded in a structure of successively more metaphysically basic truths, ultimately terminating in an intuition – remained basic to his thought. In his later work, that ultimate intuition is not the nature of a natural power, as it was in the anaclastic line example, but the intuition that establishes the existence of the knowing subject, the Cogito Argument.

4 Doubt and the quest for certainty

In the *Rules for the Direction of the Mind*, Rule 2 reads: 'We should attend only to those objects of which our minds seem capable of having certain

and indubitable cognition'. While, as we shall later see, Descartes seemed to relax this demand somewhat in his later writings, the demand for certainty was prominent throughout many of his writings. Historically, this can be seen as a reaction against important sceptical currents in Renaissance thought, the so-called 'Pyrrhonist Crisis'. In the face of the rapidly expanding boundaries of the European world in the sixteenth century, from new texts to new scientific discoveries to the discoveries of new worlds, contradictions and tensions in the intellectual world abounded, making it more and more attractive to hold, with the classical sceptics, that real knowledge is simply beyond the ability of human beings to acquire (see PYRRHONISM). Against this, Descartes asserted that real, certain knowledge is possible; though his name is associated with scepticism, it is as an opponent and not an advocate.

But though certainty was central to Descartes, the path to certainty begins with doubt. In Meditation I, entitled 'What can be called into doubt', Descartes says that 'I realised that it was necessary, once in the course of my life, to demolish everything completely and start again right from the foundations if I wanted to establish anything at all in the sciences that was stable and likely to last'. Following that, he presents a series of three sceptical arguments designed to eliminate his current beliefs in preparation for replacing them with certainties. The strategy is to undermine the beliefs, not one by one but by undermining 'the basic principles' on which they rest. While at least some of these arguments can be found in versions in the *Discourse* and in other writings by Descartes, they receive their fullest exposition in the *Meditations*.

The first argument is directed at the naïve belief that everything learned via the senses is worthy of belief. Against this Descartes points out that 'from time to time I have found that the senses deceive, and it is prudent never to trust completely those who have deceived us even once'. The second, the famous dream argument, is directed against the somewhat less naïve view that the senses are at least worthy of belief when dealing with middle-sized objects in our immediate vicinity: 'A brilliant piece of reasoning! As if I were not a man who sleeps at night . . . I plainly see that there are never any sure signs by means of which being awake can be distinguished from being asleep'. But even if I doubt the reliability of what the senses seem to be conveying to me right now, Descartes supposes, the dream argument still leaves open the possibility that there are some general truths, not directly dependent on my present sensations, that I can know. Descartes replies to this with his deceiving God argument.

This complex argument has two horns. Descartes first supposes 'the long-standing opinion that there is an omnipotent God who made me the kind of creature that I am'. Because God is omnipotent, he might have made me in such a way that I go wrong in even the simplest and most evident beliefs that I have – for example, that 2 + 3 = 5, or that a square has four sides. Though God is thought to be good, the possibility that I am so deeply prone to error seems as consistent with his goodness as the fact that I go wrong even occasionally, at least at this stage of the investigation. But what if there is no God, or what if I arose by 'fate or chance or a continuous chain of events, or by some other means'? In this case, Descartes argues, the less powerful my original cause, 'the more likely it is that I am so imperfect as to be deceived all the time'.

With this, the sceptical arguments of Meditation I are complete: 'I am finally compelled to admit that there is not one of my former beliefs about which a doubt may not properly be raised'. But, Descartes notes, 'my habitual opinions keep coming back'. It is for that reason that Descartes posits his famous evil genius: 'I will suppose therefore that not God, who is supremely good and the source of truth, but rather some evil genius of the utmost power and cunning has employed all his energies in order to deceive me'. The evil genius (sometimes translated as the 'evil demon') is introduced here not as a separate argument for doubt, but as a device to help prevent the return of the former beliefs called into doubt.

These arguments have a crucial function in Descartes' project. As he notes in the introductory synopsis of the *Meditations*, these arguments 'free us from all our preconceived opinions, and provide the easiest route by which the mind may be led away from the senses'. In this way the sceptical doubt of Meditation I prepares the mind for the certainty to which Descartes aspired. But in the *Third Replies*, responding to criticisms from Hobbes, Descartes notes two other roles that the sceptical arguments play in his thought. Descartes remarks that they are introduced 'so that I could reply to them in the subsequent Meditations'. As considered below, the deceiving God argument is answered in Meditations III and IV, and the dream argument is answered in the course of his discussion of sensation in Meditation VI. (Since Descartes, quite rightly, continued to maintain that sensation is not entirely trustworthy as a guide to how things really are, the first sceptical argument is never fully answered, though in Meditation VI he carefully sets out the conditions under which we can trust the senses.) Finally, he notes that the arguments are there as a kind of standard against which he can measure the certainty of his later conclusions: 'I wanted to show

the firmness of the truths which I propounded later on, in the light of the fact that they cannot be shaken by these metaphysical doubts'. In all these ways, Descartes presented himself as addressing the sceptic, and defending a kind of dogmatic philosophy.

5 The Cogito Argument

Descartes' philosophy begins in doubt. The first step towards certainty, the Archimedean point from which the whole structure will grow, is the discovery of the existence of the self. At the beginning of Meditation II, reflecting on the evil genius posited at the end of Meditation I, Descartes observes: 'Let him deceive me as much as he can, he will never bring it about that I am nothing so long as I think that I am something . . . I must finally conclude that this proposition, *I am*, *I exist*, is necessarily true whenever it is put forward by me or conceived in my mind'. In the earlier *Discourse* (Part IV) and the later *Principles of Philosophy* (Part I §7), this proposition has the more familiar form, 'I am thinking, therefore I exist,' or, 'ego cogito, ergo sum,' in its Latin formulation. Here, it is called the Cogito Argument.

There is considerable discussion about how exactly Descartes thought this argument functions. There are two strains of interpretation that derive directly from his texts. In the *Second Replies*, Descartes observes that 'when we become aware that we are thinking things, this is a primary notion which is not derived by means of any syllogism'. This suggests that the Cogito Argument is known immediately by direct intuition. In the *Principles* (Part I §10), however, Descartes notes that before knowing the Cogito, we must grasp not only the concepts of thought, existence and certainty, but also the proposition that 'it is impossible that that which thinks should not exist'. This suggests that the Cogito *is* a kind of syllogism, in which I infer my existence from the fact that I am thinking, and with the premise that whatever thinks must exist. Recent analytic philosophers have also been attracted to the Cogito, trying to understand its obvious allure through speech act theory and theories of demonstratives. These accounts, however, are distant from anything that Descartes himself conceived.

There is also some confusion about what the conclusion of the Cogito Argument is supposed to be. In the body of Meditation II, Descartes clearly establishes the existence of the self as a thinking thing or a mind. But the title of Meditation II, 'The nature of the human mind, and how it is better known than the body' suggests that Descartes believed that he had established that the nature of the human mind is thought. Further still, in parallel texts in the *Discourse* (Part IV) and the *Principles* (Part I §§7–8), Descartes suggests that the Cogito establishes the existence of a thinking substance distinct from the body, though in the text of Meditation II, this seems to be denied.

Though most closely associated with Descartes, the Cogito Argument may not be altogether original. A number of Descartes' contemporaries, both during his life and afterwards, noticed the connection between the Cogito and similar formulations in AUGUSTINE. However, what was important to Descartes about the Cogito is the foundational role it plays in his system. For Descartes, it is 'the first thing we come to know when we philosophise in an orderly way' (*Principles*: Part I §7). Common sense might think that the physical world of bodies, known through sensation, is more accessible to us than is the mind, a thinking thing whose existence is established, even though we have rejected the senses. But, as Descartes argues in Meditation II using the example of a piece of wax, despite our prejudices, bodies are not conceived through the senses or the imagination but through the same process of purely intellectual conception that gives us the conception of ourselves as thinking things. Furthermore, knowledge of the external world is less certain than knowledge of the mind, since whatever thought could lead us to a probable belief in the existence of bodies will lead us to believe in the existence of the self with certainty.

The project, then, is to build the entire world from the thinking self. It is important here that it is not just the mind that is the foundation, but *my* mind. In this way, the starting place of philosophy for Descartes was connected with the rejection of authority that is central to the Cartesian philosophy. In beginning with the Cogito, we build a philosophy detached from history and tradition.

6 God

The next stage in the system, as outlined in the *Meditations*, seeks to establish that God exists. In his writings, Descartes made use of three principal arguments. The first (at least in the order of presentation in the *Meditations*) is a causal argument. While its fullest statement is in Meditation III, it is also found in the *Discourse* (Part IV) and in the *Principles* (Part I §§17–18). The argument begins by examining the thoughts contained in the mind, distinguishing between the formal reality of an idea and its objective reality. The formal reality of any thing is just its actual existence and the degree of its perfection; the formal reality of an idea is thus its actual existence and degree of perfection as a mode of mind. The objective reality of an idea is the

degree of perfection it has, considered now with respect to its content. (This conception extends naturally to the formal and objective reality of a painting, a description or any other representation.) In this connection, Descartes recognized three fundamental degrees of perfection connected with the capacity a thing has for independent existence, a hierarchy implicit in the argument of Meditation III and made explicit in the *Third Replies* (in response to Hobbes). The highest degree is that of an infinite substance (God), which depends on nothing; the next degree is that of a finite substance (an individual body or mind), which depends on God alone; the lowest is that of a mode (a property of a substance), which depends on the substance for its existence. Descartes claims that 'it is manifest by the natural light that there must be at least as much reality in the efficient and total cause as in the effect of that cause'. From that he infers that there must be as much *formal* reality in the cause of an idea as there is *objective* reality in the idea itself. This is a bridge principle that allows Descartes to infer the existence of causes from the nature of the particular ideas that are in the mind, and thus are effects of some causes or another. In Meditation III, Descartes discusses various classes of ideas, one by one, and concludes that, as a finite substance, he can conceivably be the cause of all the ideas he has in his mind except for one: the idea of God. Since the idea of God is an idea of something that has infinite perfection, the only thing that can cause that idea in my mind is a thing that formally (actually) has the perfection that my idea has objectively – that is, God himself.

Descartes used two other arguments for the existence of God in his writings. In Meditation III, following the causal argument, he offers a version of the cosmological argument for those who, still blinded by the senses, may be reluctant to accept the bridge principle that his causal argument requires. (Versions of this argument are also found in *Discourse* Part IV, and in *Principles* Part I §§20–1.) This argument begins with the author's own existence, as established in Meditation II. But, the author might ask, what could have created me? It will not do, Descartes argues, to suggest that I have been in existence always, and thus I do not need a creator, since it takes as much power to sustain me from moment to moment as it does to create me anew. I could not have created myself because then I would have been able to give myself all the perfections that I so evidently lack. Furthermore, if I could create myself, then I could also sustain myself, which I do not have the power to do; being a thinking thing, if I had such a power, I would be aware of having it. My parents cannot be my creators, properly speaking, since they have neither the ability to create a thinking thing (which is all I know myself to be at this stage of the *Meditations*), nor to sustain it once created. Finally, I could not have been created by another creature of lesser perfection than God, since I have an idea of God, an idea I could not acquire from a lesser being. (Here one suspects that this cosmological argument really collapses into the first causal argument.) From this Descartes concludes 'that the mere fact that I exist and have within me an idea of a most perfect being . . . provides a very clear proof that God indeed exists'.

These first two arguments for the existence of God play a central role in the validation of reason, as discussed below. But after reason has been validated on theological grounds, Descartes presents in Meditation V a version of the ontological argument (see God, arguments for the existence of §§2–3). After reflecting on the basis of geometric reasoning, the fact that 'everything which I clearly and distinctly perceive to belong to that thing really does belong to it', Descartes concludes that this applies to the idea of God as well. Hence he concludes that 'it is quite evident that existence can no more be separated from the essence of God than the fact that its three angles equal to two right angles can be separated from the essence of a triangle, or than the idea of a mountain can be separated from the idea of a valley'. Though apparently circular in so far as its validity seems to depend on the prior arguments for the existence of God, it is not; Descartes' point is that 'even if it turned out that not everything on which I have meditated in these past days is true, I ought still to regard the existence of God as having at least the same level of certainty as I have hitherto attributed to the truths of mathematics'. As with the other two arguments, Descartes' ontological argument is also found in the *Discourse* (Part IV) and in the *Principles* (Part I §§14–16); indeed, in the *Principles* it is the first argument he gives.

As noted above, the existence of God plays a major role in the validation of reason. But it also plays a major role in two other parts of Descartes' system. As we shall later see in connection with Descartes' physics, God is the first cause of motion, and the sustainer of motion in the world. Furthermore, because of the way he sustains motion, God constitutes the ground of the laws of motion. Finally, Descartes held that God is the creator of the so-called eternal truths. In a series of letters in 1630, Descartes enunciated the view that 'the mathematical truths which you call eternal have been laid down by God and depend on Him entirely no less than the rest of His creatures' (letter to Mersenne, 15 April 1630; Descartes 1984–91 vol. 3: 23), a view that Descartes seems to have held into his mature years. While it never again gets the prominence it had in 1630, it is clearly present both

in correspondence (for example, letter to Arnauld, 29 July 1648; Descartes 1984–91 vol. 3: 358–9) and in published writings (for example, in the *Sixth Responses*).

Various commentators have proposed that Descartes was really an atheist, and that he includes the arguments for the existence of God as window dressing. While this is not impossible, the frequent appeal to God in philosophical contexts, both in private letters and in published work, suggests that it is rather unlikely.

7 The validation of reason

With the existence of God established, the next stage in Descartes' programme is the validation of reason. At the beginning of Meditation III, before proving God's existence, Descartes notes that the uncertainty that remains is due only to the fact that the meditator does not know whether or not there is a God and, if there is, if he can be a deceiver. This suggests that all one must do to restore reason and defeat the third and most general sceptical argument presented in Meditation I is to prove that there is a benevolent God. And at the end of Meditation III, after two proofs for the existence of God, Descartes concludes directly that this God 'cannot be a deceiver, since it is manifest by the natural light that all fraud and deception depend on some defect'. But this is not enough. In the course of the deceiving-God argument of Meditation I, Descartes notes that if some deception is consistent with divine benevolence, then total deception would be as well. Since it is undeniable that we do make mistakes from time to time, and are thus deceived, this raises a problem for Descartes: what, if anything, does God's benevolence and veracity guarantee?

Descartes answers this question by way of an account of error in Meditation IV. Roughly speaking, the mistakes I make are due to myself and my (improper) exercise of my free will, while the truths I come to know are because of the way God made me. More exactly, Descartes asserts that judgments depend on two faculties of the mind, 'namely, on the faculty of knowledge [or intellect] which is in me, and on the faculty of choice or freedom of the will'. A judgment is made when the will assents to an idea that is in the intellect. But the intellect is finite and limited in the sense that it does not have ideas of all possible things. On the other hand, the will is indefinite in its extent, Descartes claims: 'It is only the will or freedom of choice which I experience within me to be so great that the idea of any greater faculty is beyond my grasp'. It is in our free will that we most resemble God. In certain circumstances, Descartes held, 'a great light in the intellect is followed by a great inclination in the will', and in this way the intellect determines the will to assent. This, he thought, is a proper use of the will in judgment. In this situation, where the intellect determines the will to assent, Descartes talks of our having a clear and distinct perception of a truth. In this case, God has made us in such a way that we cannot but assent. (Clear and distinct perceptions are very close to what he calls 'intuitions' in the *Rules*, as discussed above.) But because the will has a greater extent than the intellect, and is not restrained by it, sometimes things outside the intellect move the will to assent. This is where error enters: 'The scope of the will is wider than that of the intellect; but instead of restricting it within the same limits, I extend its use to matters which I do not understand. Since the will is indifferent in such cases, it easily turns aside from what is true and good, and this is the source of my error and sin'. In this way, I am responsible for error by extending my will beyond where it belongs. God can in no way be held accountable for my mistakes any more than he can be responsible for my sins. I cannot reproach my maker for not having given me more ideas in the intellect than I have, nor can I fault him for having made me more perfect by giving me a free will. But as a result of a limited intellect and a free will, it is possible for me both to make mistakes and to sin.

As a result of this analysis of error, Descartes is able, in Meditation IV, to assert his famous principle of clear and distinct perception, an epistemological principle to replace the principles that were rejected as a result of the sceptical arguments of Meditation I: 'If I simply refrain from making a judgement in cases where I do not perceive the truth with sufficient clarity and distinctness, then it is clear that I am behaving correctly and avoiding error. But if in such cases I either affirm or deny, then I am not using my free will correctly'. With this, reason is validated, and the deceiving-God argument answered. Yet, this does not end Descartes' engagement with the sceptical arguments of Meditation I, and in Meditation VI he also addresses the question of the reliability of the senses, presents a limited validation of sensory knowledge, and answers the dream argument.

The validation of reason, central as it is to Descartes' project in the *Meditations*, has one apparent flaw: it seems to be circular. The validation of reason in Meditation IV depends on the proof of the existence of God which, in turn, depends on the proof of the existence of the self as a thinking thing. But evidently we must assume that clear and distinct perceptions are trustworthy in order to trust the Cogito and the proofs for the existence of God that ground the validation of reason – the so-called

'Cartesian Circle'. Two of the objectors to the *Meditations* noticed this point, and elicited responses from Descartes, in the *Second* and the *Fourth Replies*. Descartes' answer is not altogether clear. In the *Second Replies* he remarks, in answer to one such objection, that 'when I said that we can know nothing for certain until we are aware that God exists, I expressly declared that I was speaking only of knowledge of those conclusions' deduced by long arguments, and not of 'first principles', such as the Cogito Argument. This suggests that Descartes would exempt immediately intuitable (self-evident) propositions from the scope of the doubt of Meditation I, and use them as tools for establishing the premises of the argument that leads to the validation of reason in Meditation IV. There are serious problems with this approach. For one, it seems arbitrary to exempt self-evident propositions from the scope of doubt. Such propositions would seem to fall quite naturally among those most obvious of things that Descartes calls into doubt there; if God could create me in such a way that I go wrong when I add two and three, he could create me in such a way that I go wrong with any other self-evident belief. Furthermore, even if those propositions that are immediately evident are outside the scope of doubt, Descartes' proofs for the existence of God, necessary premises of his validation of reason, are not self-evident. These apparent problems might be either weaknesses in Descartes' response, or reasons to doubt that we have understood Descartes correctly in his responses.

The problem of circularity and the obvious problems in Descartes' apparent answer have elicited numerous examinations of the issue in the commentary literature. It is not clear just what Descartes' own solution was, nor whether or not there is a good response to the Cartesian Circle. But whatever the answer, the problem is not a superficial oversight on Descartes' part. It is a deep philosophical problem that will arise in some form or another whenever one attempts a rational defence of reason.

8 Mind and body

One of Descartes' most celebrated positions is the distinction between the mind and the body. Descartes did not invent the position. It can be found in various forms in a number of earlier thinkers. It is a standard feature of Platonism and, in a different form, is common to most earlier Christian philosophers, who generally held that some feature of the human being – its mind or its soul – survives the death of the body (see PLATO §13). But the particular features of Descartes' way of drawing the distinction and the arguments that he used were very influential on later thinkers.

There are suggestions, particularly in the *Discourse* (Part IV) and in the *Principles* (Part I §§7–8) that the distinction between mind and body follows directly from the Cogito Argument, as discussed above. However, in the *Meditations* Descartes is quite clear that the distinction is to be established on other grounds. In Meditation VI he argues as follows: I have a clear and distinct idea of myself as a thinking non-extended thing, and a clear and distinct idea of body as an extended and non-thinking thing. Whatever I can conceive clearly and distinctly, God can so create. So, Descartes argues, the mind, a thinking thing, can exist apart from its extended body. And therefore, the mind is a substance distinct from the body, a substance whose essence is thought.

Implicit in this argument is a certain conception of what it means to be a substance, a view made explicit in the *Principles* (Part I §51), which defines a substance as 'nothing other than a thing which exists in such a way as to depend on no other thing for its existence', no other thing but God, of course. In so far as the mind can exist independently of the body, it is a substance on this definition. (God is the third kind of substance, along with mind and body, though because of his absolute independence, he is a substance in a somewhat different sense.) On Descartes' metaphysics, each substance has a principal attribute, an attribute that characterizes its nature. For mind it is thought, and for body it is extension. In addition, substances have modes, literally ways of instantiating the attributes. So, for Descartes, particular ideas, particular volitions, particular passions are modes of mind, and particular shapes, sizes and motions are modes of body.

Descartes' conception of mind and body represents significant departures from the conceptions of both notions in the late scholastic thought in which he was educated. For the late scholastics, working in the Aristotelian tradition, body is composed of matter and form. Matter is that which remains constant in change, while form is that which gives bodies the characteristic properties that they have. For Descartes, however, all body is of the same kind, a substance that contains only geometric properties, the objects of geometry made concrete. The characteristic properties of particular forms of body are explained in terms of the size, shape and motion of its insensible parts (see §11 below). For the late scholastics, the mind is connected with the account of life. On the Aristotelian view, the soul is the principle of life, that which distinguishes a living thing from a dead thing; it is also taken to be the form that pertains to the living body. The mind is the rational part of the soul, that which characterizes humans, and not usually considered a genuine substance, though by most accounts, with

divine aid, it can survive the death of the body (see NOUS; PSYCHĒ). For Descartes, the majority of the vital functions are explained in terms of the physical organization of the organic body. The mind, thus, is not a principle of life but a principle of thought. It involves reason, as does the rational soul of the Aristotelians, but it also involves other varieties of thought, which pertain to other parts of the Aristotelian soul (see ARISTOTLE §17). Furthermore, it is a genuine substance, and survives the death of the body naturally and not through special divine intervention.

Mind and body are distinct because they can exist apart from one another. However, in this life, they do not. In Meditation VI Descartes observed: 'Nature also teaches me, by these sensations of pain, hunger, thirst and so on that I am not merely present in my body as a sailor is present in a ship, but that I am very closely and, as it were, intermingled with it, so that I and the body form a unit'. He sometimes went so far as to say that the human mind is the form of the human body, the only kind of form that he recognizes in nature, and that the human being – the union of a mind and a body – constitutes a genuine substance, though the context of these statements suggests that they may be made more for orthodoxy's sake than an expression of his own views (see, for example, the letter to Regius, January 1642 (Descartes 1984–91 vol. 3: 208), where he is advising Regius on the best way to answer the attacks made by the more orthodox Aristotelian Gisbertus Voëtius in connection with the controversy at Utrecht.) But be that as it may, he was clearly committed to holding that the mind and the body are united. Some of his contemporaries found it difficult to understand how two such different substances could interact and be joined. Sometimes Descartes dismissed this objection by saying that it is no more difficult than understanding how form and matter unite for the Aristotelians, something that everyone learns at school (letter to Arnauld, 29 July 1648; Descartes 1984–91 vol. 3: 358). But elsewhere, particularly in an important exchange of letters with the Princess Elisabeth of Bohemia, Descartes offered a different explanation, remarking that it is simply an empirical fact that they do unite and interact, something that we learn from everyday experience, and suggesting that just as we have innate notions that allow us to understand the notions of thinking and extended substance, we also have an innate notion that allows us to comprehend how mind and body interact, and how together they can constitute a unity (letters to Elisabeth, 21 May 1643 and 28 June 1643; Descartes 1984–91 vol. 3: 217–20, 226–9).

According to Descartes, the mind is joined to the body in one specific place: the pineal gland, a single gland in the centre of the brain, between the two lobes. This is the spot in which interaction takes place. The mind has the ability to move the pineal gland, and by doing so, to change the state of the brain in such a way as to produce voluntary motions. Similarly, the sensory organs all transmit their information to the pineal gland and, as a result of that, sensation is transmitted to the attached mind. However, because of the interconnection of the parts that make up the organic body, by virtue of being connected to the pineal gland, the mind can properly be said to be connected with the body as a whole (*Passions*: §§30–2) (see PERSONS).

9 The external world and sensation

The argument for the distinction between mind and body in Meditation VI establishes the nature of body as extension, but it does not establish the real existence of the world of bodies outside of the mind. This is the focus of the last series of arguments in the *Meditations*. The argument begins in Meditation VI with the recognition that I have 'a passive faculty of sensory perception', which would be useless unless there was also an 'active faculty, either in me or in something else' which produces the ideas of sensation. Descartes has already established in Meditation IV that the mind has only two faculties – a passive faculty of perception, and the active faculty of will. Since it is passive, perception cannot be the source of my ideas of sensation, and since sensations are involuntary, they cannot be the product of my will. So, the ideas of sense must come from somewhere else. God 'has given me a great propensity to believe that they are produced by corporeal things', and no means to correct my error if that propensity is deceptive. So, Descartes concluded, God would be a deceiver if my sensory ideas come from anything but from bodies. This argument does not prove that everything we sense about bodies is reliable, but only that 'they possess all the properties which I clearly and distinctly understand, that is, all those which, viewed in general terms, are comprised within the subject-matter of pure mathematics'. (In the *Principles* Part II §1 there is also an argument for the existence of the external world, but it is somewhat different.)

The proof of the existence of the external world tells us that, in general, bodies are the causes of our sensations and it tells us, in general, what the nature of body is. But it does not seem to tell us much about what we can (and cannot) learn about specific bodies in the world around us in specific circumstances. These questions are addressed at the end of Meditation VI in a general discussion of the reliability of sensation, the most extensive such discussion in Descartes' writings. He argues there

that the senses are given to me 'simply to inform the mind of what is beneficial or harmful for the composite of which the mind is a part; and to this extent they are sufficiently clear and distinct'. That is, while they cannot tell me anything about the real nature of things – that is for the intellect or reason to determine – they can inform me about specific features of my environment that relate to maintaining the union of my mind and body. So, for example, when the senses tell us that some particular apples are red and others green, this can give us reliable information that some may be ripe (and thus nutritious) and others not, but it cannot tell us that the one is, in its nature, red, and the other really green. Similarly, when I feel a pain in my toe, this tells me that there is damage to my toe, not that there is something resembling the sensation that is actually in the toe. Even in this, the sensation may be misleading. As Descartes points out, people sometimes feel pain in limbs even after they have been amputated.

Given the nature of the extended body, and the causal process by which pains (and other sensations) are transmitted through the body to the pineal gland, where the non-extended mind is joined to the extended body, such misleading sensations are inevitable; similar sensations in the mind can be the result of very different causal processes in the body. For example, a sensation of pain-in-the-toe can be caused either by a change in the state of the toe itself, or by an appropriate stimulation of the nerve connecting the toe to the brain at any point between the two. But, Descartes claims, though sensation is fallible, 'I know that in matters regarding the well-being of the body, all my senses report the truth much more frequently than not'. Furthermore, I can use multiple senses and memory, together with the intellect, 'which has by now examined all the causes of error' in order to weigh the evidence of the senses and use it properly. And with this, Descartes is finally able to answer the dream argument of Meditation I. For my waking experience is interconnected in a way in which my dreaming experience is not; the things I see in waking life, unlike those in dreams, come to me through all my senses, and connect with my memory of other objects. I can use this interconnectedness of waking experience, together with my intellect and my knowledge of the causes of error, to sort out veridical sensations and distinguish them from the deceptive sensory experiences of dreams. Sometimes even my waking experiences will be deceptive, of course, but we are capable of determining specific circumstances in which the senses are worthy of our trust. And so, contrary to the original doubts raised by the dreaming argument in Meditation I, there is no general reason to reject waking experience as such.

Though subordinated to reason, sensation, cast into doubt in Meditation I, re-enters as a legitimate source of knowledge about the world by the end of Meditation VI.

10 Philosophical psychology and morals

Morality was a concern of Descartes' in a variety of texts. In the third part of his *Discourse* he presents what he calls a 'provisional morality', a morality to govern our behaviour while we are in the process of revising our beliefs and coming to certainty. In the tree of philosophy in the Preface to the French edition of the *Principles*, morals is listed as one of the fruits of the tree, along with medicine and mechanics. It is also a theme in the letters he exchanged with the Princess Elisabeth of Bohemia in the mid-1640s, together with another concern – the passions, what they are and, more importantly, how to control them. These themes are intertwined again in Descartes' last major work, the *Passions of the Soul* (1649).

In one of the letters that serves as a preface to the *Passions*, Descartes announces that he will treat the passions 'only as a natural philosopher [*en physicien*], and not as a rhetorician or even as a moral philosopher'. Accordingly, the bulk of the *Passions* is taken up with detailed accounts of what the passions are, and how they arise from the connection between the human body and the human mind. As Descartes conceived them, the passions are grouped with sensation and imagination, perceptions of the mind that arise from external impulses. In this respect, Descartes differed radically from the Aristotelian scholastic philosophers who attached the passions to the appetitive faculty rather than the perceptive. But though grouped with other perceptions, the ones that concern Descartes in this treatise are a special group of perceptions, 'those whose effects we feel as being in the soul itself, and for which we do not normally know any proximate cause to which we can refer them', those 'which are caused, maintained, and strengthened by some movement of the spirits'(*Passions*: §§25, 27). (The 'spirits' in question are the animal spirits, a fluid matter that played a major role in Descartes' biology.) The principal effect of the passions is to 'move and dispose the soul to want the things for which they prepare the body. Thus the feeling of fear moves the soul to want to flee, that of courage to want to fight' and so on (*Passions*: §40). As with sensations, the passions of the soul play a role in the preservation of the mind–body union: 'The function of all the passions consists solely in this, that they dispose our soul to want the things which nature deems useful for us, and to persist in this volition; and the same agitation of the spirits which

normally causes the passions also disposes the body to make movements which help us to attain these things' (*Passions*: §52).

For the schoolmen, the passions pertained to the appetitive faculty, and were principally organized around a distinction between the 'irascible' and the 'concupiscent' appetites. Descartes, however, was attempting to fashion a conception of the passions based on a very different conception of the soul, one in which there is no distinction among appetites (*Passions*: §68). His categorization of the passions was based on a list of six primitive passions, which pertain to the perceptive rather than to the appetitive faculty: wonder, desire, love and hatred, joy and sadness – 'all the others are either composed from some of these six or they are species of them' (*Passions*: §69). Much of his attention in the short book is directed at accounts of what each of these basic passions is, what it feels like and its physiological causes and effects in the body, and how all the other passions can be understood in terms of the six basic ones.

But although Descartes presents himself as examining the passions '*en physicien*', there is a moral dimension to the discussion as well. Part of the motivation for the examination of the passions is their control. While the passions, like everything given to us by God, can contribute to our wellbeing, they can also be excessive and must be controlled (*Passions*: §211). While the passions are not under our direct control, by understanding what they are and how they are caused we can learn indirect means for controlling them (*Passions*: §§45–50, 211). This, Descartes asserts, is the 'chief use of wisdom, [which] lies in its teaching us to be masters of our passions and to control them with such skill that the evils which they cause are quite bearable, and even become a source of joy' (*Passions*: §212). Important in this process is what Descartes calls *générosité*, best translated as 'nobility'. *Générosité* is the knowledge that all that belongs to us, properly speaking, is our own free will, and the resolution to use it well, 'that is, never to lack the will to undertake and carry out whatever one judges to be best' (*Passions*: §53). Understood in this way, *générosité* is both a passion (an immediate feeling) and a virtue ('a habit of the soul which disposes it to have certain thoughts') (*Passions*: §§160–1). The person who has *générosité* 'has very little esteem for everything that depends on others', and as a result, Descartes claims, is able to control their passions (*Passions*: §156).

11 Physics and mathematics

To his contemporaries, Descartes was as well known for his system of physics as he was for the metaphysical views that are now more studied. Indeed, as he indicates in the Preface to the French edition of the *Principles*, metaphysics constitutes the roots of the tree of philosophy, but the trunk is physics.

Descartes' physics was developed in two main places. The earliest is in the treatise *Le Monde* (*The World*) which he suppressed when Galileo was condemned for Copernicanism in 1633, though summarized in Part V of the *Discourse*. Later, in the early 1640s, he presented much of the material in a more carefully worked-out form, in Parts II, III and IV of the *Principles*. Like the physical thought of many of his contemporaries, his physics can be divided into two parts – a general part, which includes accounts of matter and the general laws of nature, and a specific part, which includes an account of particular phenomena.

The central doctrine at the foundations of Descartes' physics is the claim that the essence of body is extension (discussed in §8 above). This doctrine excludes substantial forms and any sort of sensory qualities from body. For the Schoolmen there are four primary qualities (wet and dry, hot and cold) which characterize the four elements. For Descartes, these qualities are sensations in the mind, and only in the mind; bodies are in their nature simply the objects of geometry made real. Descartes also rejected atoms and the void, the two central doctrines of the atomists, an ancient school of philosophy whose revival by Gassendi and others constituted a major rival among contemporary mechanists. Because there can be no extension without an extended substance, namely body, there can be no space without body, Descartes argued. His world was a plenum, and all motion must ultimately be circular, since one body must give way to another in order for there to be a place for it to enter (*Principles* II: §§2–19, 33). Against atoms, he argued that extension is by its nature is indefinitely divisible: no piece of matter in its nature is indivisible (*Principles* II: §20). Yet he agreed that, since bodies are simply matter, the apparent diversity between them must be explicable in terms of the size, shape and motion of the small parts that make them (*Principles* II: §§23, 64) (see LEIBNIZ, G.W. §4).

Accordingly, motion and its laws played a special role in Descartes' physics. The essentials of this account can be found in *The World*, but it is set out most clearly in the *Principles*. There (*Principles* II: §25), motion is defined as the translation of a body from one neighbourhood of surrounding bodies into another. Descartes is careful to distinguish motion itself from its cause(s). While, as we have seen, motion is sometimes caused by the volition of a mind, the general cause of motion in the inanimate world is God, who creates bodies and

their motion, and sustains them from moment to moment. From the constancy of the way in which God sustains motion, Descartes argues, the same quantity of motion is always preserved in the world, a quantity that is measured by the size of a body multiplied by its speed (*Principles* II: §36). To this general conservation law he adds three more particular laws of nature, also based on the constancy by which God conserves his creation. According to the first law, everything retains its own state, in so far as it can. As a consequence, what is in motion remains in motion until interfered with by an external cause, a principle directly opposed to the Aristotelian view that things in motion tend to come to rest (*Principles* II: §§37–8). According to the second law, bodies tend to move in rectilinear paths, with the result that bodies in circular motion tend to move away at the tangent (*Principles* II: §39). The first and second laws together arguably constitute the first published statement of what NEWTON later called the law of inertia. Descartes' third law governs the collision between bodies, specifying when one body imposes its motion on another, and when two bodies rebound from one another without exchanging motion. The abstract law is followed by seven specific rules covering special cases (*Principles* II: §§40–52). Though the law of collision turns out to be radically inadequate, it casts considerable light on Descartes' conception of the physical world. One of the determinants of the outcome of a collision is what Descartes calls the 'force' of a body, both its force for continuing in motion, and its resistance to change in its motion (*Principles* II: §43). The role of such forces in Descartes' mechanist world has generated much discussion, since they would seem to be completely inconsistent with Descartes' view that the essence of body is extension alone.

These general accounts of matter and motion form the basis of Descartes' physical theories of particular phenomena. The *Principles* goes on to explain how the earth turns around the sun in an enormous fluid vortex and how the light that comes from the sun is nothing but the centrifugal force of the fluid in the vortex, with ingenious explanations of many other particular phenomena in terms of the size, shape and motion of their parts. Other works contain further mechanistic explanations, for example of the law governing the refraction of light (*Dioptrics* II) and the way colours arise in the rainbow (*Meteors* VIII).

Descartes' hope was that he could begin with an assumption about how God created the world, and then deduce, on the basis of the laws of motion, how the world would have to have come out (*Discourse* V, VI; *Principles* III: §46). But this procedure caused some problems. It is not easy to specify just how God might have created the world – whether the particles that he first created were of the same size, for example, or of every possible size. Furthermore, any hypothesis of this sort would seem to be inconsistent with the account of creation in Genesis (*Principles* III: §§43–7). These difficulties aside, it seemed obvious to Descartes how to proceed. For example, from his denial of the vacuum it would seem to follow that bodies in motion would sort themselves out into circular swirls of matter, the vortices which were to explain the circulation of the planets around a central sun. Similarly, Descartes used the tendency to centrifugal motion generated by the circular motion of the vortex to explain light, which, he claimed, was the pressure of the subtle matter in the vortex. But the very complexity of the world militates against the full certainty that Descartes originally sought, particularly when dealing with the explanation of particular phenomena, such as the magnet. Indeed, by the end of the *Principles*, it can seem that he has given up the goal of certainty and come to accept the kind of probability that he initially rejected (*Principles* IV: §204–6).

Central to Descartes' physics is his rejection of final causes: 'When dealing with natural things we will, then, never derive any explanations from the purposes which God or nature may have had in view when creating them. For we should not be so arrogant as to suppose that we can share in God's plans' (*Principles* I: §28). The emphasis on efficient causes was to prove very controversial later in the century.

One especially curious feature of Descartes' physics, however, is the lack of any substantive role for mathematics. Descartes was one of the great mathematicians of his age. While it is, perhaps, anachronistic to see modern analytic geometry and so-called Cartesian coordinates in his *Geometry* (1637), there is no question but that it is a work of real depth and influence. In it he shows how one could use algebra to solve geometric problems and geometry to solve algebraic problems by showing how algebraic operations could be interpreted purely in terms of the manipulation and construction of line segments. In traditional mathematics, if a quantity was represented as a given line, then the square of that quantity was represented as a square constructed with that line as a side, and the cube of the quantity represented as a cube constructed with that line as an edge, effectively limiting the geometric representation of algebraic operations to a very few. By demonstrating how the square, cube (and so on) of a given quantity could all be represented as other lines, Descartes opened the way to a more complete unification of algebra and geometry. Also important to his mathematical work was the notion of analysis. Descartes saw himself as

reviving the work of the ancient mathematician, Pappus of Alexandria, and setting out a methodology for the solution of problems, a methodology radically different from the Euclidean style of doing geometry in terms of definitions, axioms, postulates and propositions, which he regarded as a method of presentation rather than a method of discovery. According to the procedure of analysis, as Descartes understood it, one begins by labelling unknowns in a geometric problem with letters, setting out a series of equations that involve these letters, and then solving for the unknowns to the extent that this is possible.

Unlike his contemporary, Galileo, or his successors, Leibniz and Newton, Descartes never quite figured out how to apply his mathematical insights to the physical world. Indeed, it is a curious feature of his tree of knowledge that, despite the central place occupied by mathematics in his own accomplishments, it seems to have no place there.

12 Life and the foundations of biology

The last part of the Cartesian programme was his biology. First presented in the *Treatise on Man*, part of *The World* project which was abandoned in 1633 when Galileo was condemned, Descartes intended to rework some of that material and publish it – as Parts V and VI of the *Principles* under the title 'De Homine'. Although he never finished this rewriting, it is clear from the notes left behind that it was very much on his mind in years that preceded his sudden and premature death.

His hope seems to have been to show how, from matter and the laws of motion alone, life would arise spontaneously as matter came to organize itself in an appropriate way (*Discourse* V). Unfortunately he never worked out this view, suggestive of later theories of evolution, in any detail. Yet, he was quite clear that all the functions of life (with the exception of thought and reason in humans) are to be explained not in terms of the soul, the principle of life, but in terms of matter in motion. Accordingly, in the *Treatise on Man*, he accounts for a variety of phenomena, including digestion, involuntary motion, the action of the heart, and sense perception, in purely mechanical terms. (Summarized in *Discourse* Part V, with special emphasis on the circulation of the blood.)

While Descartes' biology was controversial among his contemporaries, one aspect was especially so. According to his account, there is only one kind of soul in the world, the rational soul, which humans and angels have and animals do not. Humans are organic machines, collections of matter organized so as to be able to perform vital functions, attached to rational souls. Animals, on the other hand, are just machines: their behaviour is purely mechanical and they are, strictly speaking, incapable of conscious experience of any sort (*Discourse* V).

13 The Cartesian heritage

It is difficult to overestimate the influence of Descartes. In philosophy, the Cogito Argument signalled the centrality of the self and the rejection of authority from without, the authority of both texts and teacher. For physics, Descartes represented the rejection of the scholastic physics of matter and form, and its replacement by a mechanistic physics of matter and motion. So in biology he stood for mechanism and the rejection of Aristotelian vitalism.

Descartes had many followers who took his ideas (as they understood them) as dogma, and developed them as they thought he would have wanted them to do. The most important centres of Cartesian thought were France, where he was remembered as a countryman, despite his long absence, and the Netherlands, where he had lived. In France, his thought was carried on by a circle around Claude Clerselier, who gathered and published his letters as well as other works. Louis de La Forge commented on Descartes' physiology, and wrote a Cartesian treatise on the mind, extending Descartes' ideas. Gerauld de Cordemoy, tried to blend Cartesian philosophy with atomism, to the puzzlement of most of his contemporaries. Jacques Rohault was influential in Cartesian physics well after Newton had published the work that would eventually eclipse such theories. Other followers, mainly in the Low Countries, include Henricus Regius, considered Cartesian by many despite Descartes' public rejection; Adriaan Heereboord, one of Descartes' partisans in Leiden; Johannes de Raey, one of those who attempted to reconcile Descartes with the true philosophy of Aristotle; and Johannes Clauberg, who recast Cartesianism into more scholastic garb. There were many more minor Cartesians of various nationalities. Late seventeenth-century Europe was flooded with paraphrases of and commentaries on Descartes' writings.

Other more independent thinkers were strongly influenced by Descartes without explicitly being followers. The best-known such figure is probably Nicolas Malebranche. While his thought owes much to other influences, particularly to seventeenth-century Augustinianism, in his *Recherche de la vérité* (Search after Truth) (1674–5) he follows Descartes in offering a critique of the senses, rejecting the authority of tradition, and appealing to clear and distinct perceptions. Descartes was also an important influence on the Cambridge Platonist

Henry More, who regarded Descartes' philosophy, in particular his distinction between mind and body, as support for his own attacks on materialism (see CAMBRIDGE PLATONISM). SPINOZA, too, was influenced by Descartes. His first published book was a commentary on Descartes' *Principles*, and although he later moved well outside the Cartesian camp, Descartes' doctrines helped to structure his mature thought. Spinoza's metaphysical vocabulary (substance, attribute and mode) is borrowed from Descartes, as is the centrality of the attributes of thought and extension in his metaphysics.

While many of Descartes' partisans tried to remain orthodox, there is at least one doctrine characteristic of later Cartesianism that Descartes himself probably did not hold, namely, occasionalism (see OCCASIONALISM). Malebranche and the Flemish Cartesian Arnold Geulincx are most often associated with the doctrine, but it appears in Cartesian writings long before theirs. According to occasionalism, God is the only active causal agent in the world; finite minds and bodies are not real causes, but only occasions for God to exercise his causal efficacy. Motivated by the picture of divine sustenance from moment to moment that underlies Descartes' derivation of the laws of motion, together, perhaps, with general worries about the efficacy of finite causes and specific worries about mind–body interaction, occasionalism became a standard doctrine. Though often also attributed to Descartes himself, the grounds for doing so are rather slim.

Descartes' mark can also be seen among his opponents. He was clearly a target of Hobbes' materialism and sensationalism in, for example, Part I of *Leviathan* (1651). His epistemology and treatment of God were explicitly targeted by PASCAL in the *Pensées* (1658–62, published 1670). Leibniz, too, attacked his physics, his rejection of formal logic, his conception of body and his conception of the mind, among many other things. The inadequacy of the Cartesian philosophy is a constant subtext to Locke's *Essay Concerning Human Understanding* (1689), particularly in his discussion of our knowledge of mind and his rejection of the dogmatic claim to know the essences of substances. In natural philosophy, Newton's early writings show a careful study of Descartes' writings, particularly those on motion, and book II of his *Principia* was devoted to a refutation of the vortex theory of planetary motion. Between around 1650 and the eclipse of Cartesian philosophy some time in the early eighteenth century, it was simply impossible to write philosophy without reacting in some way to Descartes.

DESCRIPTIONS

Introduction

'Definite descriptions' are noun phrases of the form 'the' + noun complex (for example, 'the finest Greek poet', 'the cube of five') or of the form possessive + noun complex (for example, 'Sparta's defeat of Athens'). As Russell realized, it is important to philosophy to be clear about the semantics of such expressions. In the sentence 'Aeschylus fought at Marathon', the function of the subject, 'Aeschylus', is to refer to something; it is a referential noun phrase (or 'singular term'). By contrast, in the sentence 'Every Athenian remembers Marathon', the subject noun phrase, 'every Athenian', is not referential but quantificational. Definite descriptions appear at first sight to be referential. Frege treated them referentially, but Russell held that they should be treated quantificationally in accordance with his theory of descriptions, and argued that certain philosophical puzzles were thereby solved.

1 Frege

Gottlob Frege provided the first systematic account of quantification in natural language and the first

systematic theory of reference (Über Sinn und Bedeutung 1892). The class of 'singular terms' (referential noun phrases), for Frege, was delimited by a set of logical tests (for example, the licensing of existential generalization) and was recursive. It included ordinary proper names and definite descriptions. Thus '5', 'the cube of 5', 'Aeschylus' and so on were all singular terms.

If a description ⌜the ***F***⌝ is referential, then it is natural to take its reference to be the unique entity satisfying '*F*'; a sentence ⌜The ***F*** is ***G***⌝ is true if and only if that entity is *G*. But what if no entity, or more than one entity, satisfies the descriptive condition, as in (1) or (2)?

(1) *The largest prime number* lies between 10^{23} and 10^{27}.

(2) *The man who landed on the moon* was American.

Such descriptions are said to be 'improper'. Frege considered it a defect of natural language that it permits the possibility of improper terms. As far as his own logical system was concerned, he thought it essential that every formula have a truth-value, and so he insisted that every singular term have a reference (or meaning): he stipulated that a specified object in the range of the quantifier(s) serve as the referent of every improper description. While this stipulation proved useful for his formal system, Frege recognized that some other account of improper descriptions in ordinary language was needed. Once he had made his distinction between the 'sense' and 'reference' of an expression, he suggested that an improper term has a sense but no reference (see FREGE, G. §3; SENSE AND REFERENCE). The main problem with this proposal is that it predicts, rather counterintuitively, that any sentence containing an improper term (in a transparent context) lacks a truth-value. For example, it predicts that (1) and (2) above lack truth-values.

2 Russell's theory of descriptions: informal characterization

Like Frege, Bertrand RUSSELL thought it important to explain how a sentence such as (1) or (2) could be meaningful. At one time he entertained the idea of a realm of non-existent entities to serve as the referents of descriptions such as 'the largest prime number' and 'the round square'; but by 1905 he thought this idea conflicted with a 'robust sense of reality' and his theory of descriptions came about, in part, as an attempt to purify his ontology (see EXISTENCE).

On Russell's account, descriptions are not singular terms at all but phrases that logical analysis reveals to be quantificational: if ⌜the ***F***⌝ is a definite description and ⌜...is ***G***⌝ is a predicate phrase, then the proposition expressed by an utterance of ⌜The ***F*** is ***G***⌝ is equivalent, says Russell, to the proposition expressed by an utterance of ⌜There is exactly one *F*, and everything that is *F* is *G*⌝. That is, ⌜The *F* is *G*⌝ is analysed as

(3) $(\exists x)((\forall y)(Fy \leftrightarrow y = x) \& Gx)$.

The proposition expressed by ⌜The ***F*** is ***G***⌝ is 'general' ('object-independent') rather than 'singular' ('object-dependent') in the sense that there is no object for which its grammatical subject stands; upon whose existence that of the proposition expressed depends. Unlike a singular term, a definite description, even if it is in fact satisfied by a unique object, does not actually *refer* to that object. It is as wrong, on Russell's account, to inquire into the referent of ⌜the ***F***⌝ as it is to inquire into the referent of ⌜every ***F***⌝ or ⌜no ***F***⌝.

On Russell's account, sentences containing improper descriptions have truth-values. For example, (1) above is false as it is not the case that there exists a largest prime number. Similarly, sentence (2) is false as it is not the case that there exists exactly one man who landed on the moon.

Russell's theory opens up the possibility of accounting for certain *de dicto/de re* ambiguities in terms of scope permutations (see DE RE/DE DICTO). For example, (4) below may be analysed as either (5) or (6), according to whether the description 'the largest prime number' is given large or small scope with respect to 'John thinks that':

(4) John thinks that the largest prime number lies between 10^{23} and 10^{27}.

(5) $(\exists x)((\forall y)(\text{largest-prime } y \leftrightarrow y = x)$ & John thinks that: x lies between 10^{23} and 10^{27}).

(6) John thinks that: $(\exists x)((\forall y)(\text{largest-prime } y \leftrightarrow y = x)$ & x lies between 10^{23} and 10^{27}).

(5) is false; but (6) may be true. Thus Russell is able to explain the intuitive ambiguity of (4) and avoid positing an ontology that includes such things as a largest prime number. Smullyan points out that Russell's theory similarly explains *de dicto/de re* ambiguities in modal contexts, for example, in 'The number of planets is necessarily odd' (see MODAL LOGIC).

Russell came to treat ordinary proper names as 'disguised' or 'truncated' descriptions. For example, the name 'Cicero' might be analysed as the description 'the greatest Roman orator', while the coreferential name 'Tully' might be analysed as the description 'the author of *De Fato*'. On the face of it, this provided Russell with accounts (not

dissimilar to Frege's) of why 'Cicero was bald' and 'Tully was bald' differ in informativeness, and of why (7) and (8) need not agree in truth-value:

(7) John believes Cicero was bald.

(8) John believes Tully was bald.

In the light of Kripke's work on names and necessity, it is widely held that descriptive analyses of proper names cannot succeed (see KRIPKE, S.A.; PROPER NAMES). There is good reason, however, to think that at least some pronouns anaphorically linked to (referring back to), but not bound by, quantified noun phrases are understood in terms of definite descriptions (see Neale 1990).

3 Russell's theory of descriptions: formal characterization

On Russell's account, descriptions are 'incomplete' symbols; they have 'no meaning in isolation', that is, they do not stand for things. In *Principia Mathematica* (1910–13), descriptions are represented by quasi-singular terms of the form '$(\imath x)(Fx)$', which can be read as 'the unique x which is F'. Superficially, the iota-operator is a variable-binding device for forming a term from a formula. A predicate symbol 'G' may be prefixed to a description '$(\imath x)(Fx)$' to form a formula '$G\ (\imath x)(Fx)$', which can be expanded in accordance with a suitable 'contextual definition'. (To define an expression ζ contextually is to provide a procedure for converting any sentence containing occurrences of ζ into an equivalent sentence that is ζ-free.)

The analysis in (3) above does not constitute a final contextual definition of '$G\ (\imath x)(Fx)$' because of the possibility of scope ambiguity where a formula containing a description is itself a constituent of a larger formula (see SCOPE). Scope ambiguity is conveniently illustrated with descriptions in the context of negation. For a genuine singular term α, there is no difference between wide and narrow scope negation: α is not-F just in case it is not the case that α is F. For a description, however, there is a formal ambiguity. Let 'Kx' represent 'x is a king of France' and 'Wx' represent 'x is wise'. Then the formula '$\neg W\ (\imath x)(Kx)$' ('The king of France is not wise') is ambiguous between (9) and (10):

(9) $(\exists x)((\forall y)(Ky \leftrightarrow y = x)\ \&\ \neg Wx)$

(10) $\neg(\exists x)((\forall y)(Ky \leftrightarrow y = x)\ \&\ Wx)$.

These are not equivalent: only (10) can be true when there is no king of France. In *Principia Mathematica*, the scope of a description is specified by appending a copy of it within square brackets to the front of the formula that constitutes its scope. Thus (9) and (10) are represented as (11) and (12) respectively:

(11) $[(\imath x)(Kx)]\neg\{W(\imath x)(Kx)\}$

(12) $\neg\{[(\imath x)(Kx)]W(\imath x)(Kx)\}$.

In (11) the description has what Russell calls a 'primary occurrence' by virtue of having scope over the negation; in (12) the description has a 'secondary occurrence' by virtue of lying within the scope of the negation. Where a description has smallest possible scope, it is conventional to omit the scope marker; thus (12) can be reduced to '$\neg W(\imath x)(Kx)$'.

With the matter of scope behind us, the theory of descriptions can be stated exactly:

$$[(\imath x)(\phi x)]G(\imath x)(\phi x) =_{\mathrm{df}} (\exists x)((\forall y)(\phi y \leftrightarrow y = x)\ \&\ Gx),$$

where φ is a formula. On Russell's account, there is no possibility of a genuine referring expression failing to refer, so no predicate letter in the language of *Principia Mathematica* stands for 'exists'. Russell introduces a symbol 'E!' ('E shriek') that may be combined with a description to create a well-formed formula. Thus

$$E!(\imath x)(\phi x) =_{\mathrm{df}} (\exists x)(\forall y)(\phi y \leftrightarrow y = x).$$

'E!' allows a treatment of negative existentials. (According to Russell, an utterance of 'The king of France does not exist' made today would be true precisely because there is no king of France.) Successive applications will allow any well-formed formula containing a definite description to be replaced by an equivalent formula that is description-free.

It is often objected that Russell's theory, which substitutes complex quantificational structure for 'the', is unfaithful to surface syntax. The objection is engendered by an insufficiently keen appreciation of the distinction between a theory and its formal implementation. The extent of the mismatch between 'The king is wise' and its analysis

(13) $(\exists x)((\forall y)(\text{king } y \leftrightarrow y = x)\ \&\ \text{wise } x)$

has nothing to do with descriptions *per se*. In order to characterize the logical forms of even 'some philosophers are wise' and 'every philosopher is wise' in the predicate calculus we have to use formulas containing sentence connectives, no counterparts of which occur in the surface forms of the sentences:

(14) $(\exists x)(\text{philosopher } x\ \&\ \text{wise } x)$

(15) $(\forall x)(\text{philosopher } x \rightarrow \text{wise } x)$.

And when we formalize sentences such as 'Just two philosophers are wise', we find much more complexity than there is in surface syntax:

(16) $(\exists x)(\exists y)$[philosopher x & philosopher y & wise x & wise y & $(\forall z)$((philosopher z & wise z) $\rightarrow z = x \vee z = y$)].

The supposed problem about descriptions, then, is in fact a symptom of a larger problem involving the application of first-order logic to sentences of ordinary language.

Work on 'generalized' quantification provides a solution to the larger problem (as well as treatments of quantifiers such as 'most' that cannot be handled within first-order logic; see QUANTIFIERS, GENERALIZED). Natural language quantification is normally restricted: we talk about all philosophers or most poets, not about all or most entities. A simple modification of the predicate calculus yields a language – call it 'RQ' – that captures this fact while retaining the precision of regular first-order logic. In RQ, a determiner such as 'some', 'every' or 'no' combines with a formula to create a restricted quantifier such as '[every x: philosopher x]'. And such a quantifier may combine with a formula to form a formula:

(17) [every x: philosopher x] (wise x).

The viability of such a language shows that the language of *Principia Mathematica* is not essential to the theory of descriptions. Since the word 'the' is a one-place quantificational determiner (as are 'some', 'every', 'no' and so on), RQ can treat 'the' as combining with a formula 'king x' to form a restricted quantifier '[the x: king x]'. The sentence 'The king is wise' will then be represented as

(18) [the x: king x] (wise x).

Different scope possibilities are easily captured. For instance, 'The king is not wise' is ambiguous between (19) and (20):

(19) [the x: king x] $\neg$ (wise x)

(20) $\neg$ [the x: king x](wise x).

Using a formal language in which descriptions are treated as restricted quantifiers does not mean abandoning Russell's view that descriptions are 'incomplete symbols' that 'disappear on analysis'. Rather, treating descriptions as restricted quantifiers results in an explanation of where his theory of descriptions fits into a systematic account of natural language quantification, a theory in which 'every', 'some', 'most', 'a', 'the' and so on are members of a unified syntactic and semantic category.

4 Strawson's theory and criticisms of Russell

As part of a broad critique of the idea that the semantics of formal languages can be used to analyse the meanings of statements of natural language, P.F. STRAWSON argued against Russell's theory of descriptions on the grounds that (1) it fails to recognize that referring is something done by speakers and not expressions, (2) it fails to do justice to the way speakers ordinarily use sentences containing descriptions to make statements (speakers use descriptions to refer, not to quantify) and (3) it rides roughshod over important distinctions, such as the distinction between the meaning of a sentence σ and the statement made by a particular use of σ.

Using as an example 'The present king of France is wise', Strawson argues that Russell's theory is thwarted because the same sentence can be used to say something true on one occasion and something false on another. It is certainly true that Russell paid little attention to the distinction between the linguistic meaning of a sentence type and the proposition expressed by a particular dated utterance of that sentence type; but it was the latter that actually concerned him, and Strawson could get no mileage out of Russell's inattention to the distinction. The fact that a description (or any other quantified noun phrase) may contain an indexical component ('the *present* king of France', 'every man *here*', and so on) illustrates that some descriptions are subject to both the theory of descriptions and a theory of indexicality (see DEMONSTRATIVES AND INDEXICALS). Thus contextual features play a role in fixing the proposition expressed. And this can be true also if the overt indexical element is missing, as in 'The king of France is wise'.

This appreciation of contextual factors forms the basis of the Russellian response to a second Strawsonian objection. According to this, someone who uses a description ⌜the F⌝ typically intends to refer to some object or other and say something about it; there is no question of claiming that some object uniquely satisfies F. Someone who says 'The table is covered with books', for instance, does not express a proposition that entails the existence of exactly one table. But, Strawson claimed, it is a part of the meaning of ⌜the F⌝ that such an expression is used correctly only if there is an F. If this condition is not satisfied – if the 'presupposition' that there is an F is false – a use of ⌜The F is G⌝ cannot be considered to express a proposition that is either true or false. The Russellian response to Strawson is that descriptions such as 'the table' are often understood as elliptical uses of fuller descriptions such as 'the table over there', 'the table in front of me' and so on; or else they are evaluated with

respect to a restricted domain of discourse. Again the phenomenon is not confined to descriptions, but is found with quantified noun phrases more generally.

Strawson's original 1950 statement of his own theory contains an interesting ambiguity. He can be understood as claiming either that no proposition is expressed, or that a proposition which is neither true nor false is expressed, when someone uses a sentence containing an empty description. A second ambiguity comes with the notion of 'presupposition'. This can be viewed as an epistemological or pragmatic relation between a person and a statement, or as a logical relation between two statements (see PRESUPPOSITION). An epistemological or pragmatic notion of presupposition appears to have no bearing on the semantic issues Strawson wanted to address when he challenged Russell.

The Strawsonian position faces some serious obstacles. If someone were to utter (21) below right now, they would unquestionably say something false.

(21) The king of France shot my cat last night.

But on Strawson's account, the speaker will have expressed no proposition because the presupposition that there is a unique king of France is false. Descriptions occurring in the context of attitude verbs create a similar problem. For example, someone might utter a true statement using (22):

(22) Ponce de León thought the fountain of youth was in Florida,

so the presence of an empty description does not always result in a failed speech act. This is something Strawson came to concede. In order to reduce the number of incorrect predictions made by his earlier theory, he suggested that the presence of an empty description sometimes renders the proposition expressed false and at other times prevents a proposition from being expressed at all (sometimes ⌜The ***F*** is ***G***⌝ *entails* the existence of a unique *F*, and at other times it (only) *presupposes* it).

5 Ambiguity theories

Consideration of the behaviour of descriptions in non-extensional contexts and the possibility of misdescribing an individual as the *F*, but successfully communicating something about that individual, has led some philosophers (for example, Donnellan 1966) to suggest that descriptions are sometimes quantificational, at other times referential. When ⌜the ***F***⌝ is used in the Russellian way, the proposition expressed is general (object-independent); when it is used referentially the proposition expressed is singular (object-dependent). Donnellan considers examples such as the following: (1) A detective discovers Smith's mutilated body but has no idea who killed him. Looking at the body, he exclaims, 'The murderer is insane'. (2) Jones is on trial for Smith's murder; I am convinced of his guilt; hearing Jones ranting in court, I say, 'The murderer is insane'. On Donnellan's account, in case (1) the description is being used attributively; in case (2) it is being used referentially. Cases such as (2), it is argued, cannot be treated in accordance with Russell's theory. Following Grice, however, many have argued (1) that so-called referential uses of descriptions can usually be accommodated within Russell's theory by invoking a distinction between the proposition expressed by (an utterance of) a sentence on a given occasion and the proposition the speaker primarily intends to communicate on that occasion; (2) that the phenomenon of referential usage is not specific to definite descriptions, but arises with quantified noun phrases quite generally; (3) that the referential/attributive distinction is neither exclusive nor exhaustive; and (4) that no such distinction can do the work of Russell's notion of the scope of a description. It would seem, then, that something very close to Russell's theory will probably form a component of any finally acceptable theory.

DESIRE

If an agent is to be moved to action, then two requirements have to be fulfilled: first, the agent must possess beliefs about the way things actually are, about the actions possible given the way things are, and about the likely effects of those actions on how things are; and, second, the agent must have or form desires to change the way things are by resorting to this or that course of action. The beliefs tell the agent about how things are and about how

they can be altered; the desires attract the agent to how things are not but can be made to be.

This rough sketch of beliefs and desires is widely endorsed in contemporary philosophy; it derives in many ways from the seminal work of the eighteenth-century Scottish philosopher David Hume. The striking thing about it, from the point of view of desire, is that it characterizes desire by the job desire does in collaborating with belief and thereby generating action: it characterizes desire by function, not by the presence of any particular feeling. The account raises a host of questions. Is desire an entirely different sort of state from belief, for example, and from belief-related states like habits of inference? Does desire have to answer to the considerations of evidence and truth that are relevant to belief and inference? How does desire relate to preference and choice? And how does desire relate to the values that we ascribe to different courses of action and that influence us in what we do?

DETERMINISM AND INDETERMINISM

Over the centuries, the doctrine of determinism has been understood, and assessed, in different ways. Since the seventeenth century, it has been commonly understood as the doctrine that every event has a cause; or as the predictability, in principle, of the entire future. To assess the truth of determinism, so understood, philosophers have often looked to physical science; they have assumed that their current best physical theory is their best guide to the truth of determinism. It seems that most have believed that classical physics, especially Newton's physics, is deterministic. And in this century, most have believed that quantum theory is indeterministic. Since quantum theory has superseded classical physics, philosophers have typically come to the tentative conclusion that determinism is false.

In fact, these impressions are badly misleading. The above formulations of determinism are unsatisfactory. Once we use a better formulation, we see that there is a large gap between the determinism of a given physical theory, and the bolder, vague idea that motivated the traditional formulations: the idea that the world in itself is deterministic. Admittedly, one can make sense of this idea by adopting a sufficiently bold metaphysics; but it cannot be made sense of just by considering determinism for physical theories.

As regards physical theories, the traditional impression is again misleading. Which theories are deterministic turns out to be a subtle and complicated matter, with many open questions. But broadly speaking, it turns out that much of classical physics, even much of Newton's physics, is indeterministic. Furthermore, the alleged indeterminism of quantum theory is very controversial: it enters, if at all, only in quantum theory's account of measurement processes, an account which remains the most controversial part of the theory.

DEWEY, JOHN (1859–1952)

The philosophy of John Dewey is original and comprehensive. His extensive writings contend systematically with problems in metaphysics, epistemology, logic, aesthetics, ethics, social and political philosophy, philosophy and education, and philosophical anthropology. Although his work is widely read, it is not widely understood.

Dewey had a distinctive conception of philosophy, and the key to understanding and benefiting from his work is to keep this conception in mind. A worthwhile philosophy, he urged, must be practical. Philosophic inquiry, that is, ought to take its point of departure from the aspirations and problems characteristic of the various sorts of human activity, and an effective philosophy would develop ideas responsive to those conditions. Any system of ideas that has the effect of making common experience less intelligible than we find it to be is on that account a failure. Dewey's theory of inquiry, for example, does not entertain a conception of knowledge that makes it problematic whether we can know anything at all. Inasmuch as scientists have made extraordinary advances in knowledge, it behoves the philosopher to find out exactly what scientists do, rather than to question whether they do anything of real consequence.

Moral philosophy, likewise, should not address the consternations of philosophers as such, but the characteristic urgencies and aspirations of common life; and it should attempt to identify the resources and limitations of human nature and the environment with which it interacts. Human beings might then contend effectively with the typical perplexities and promises of mortal existence. To this end, Dewey formulated an exceptionally innovative and far-reaching philosophy of morality and democracy.

The subject matter of philosophy is not philosophy, Dewey liked to say, but 'problems of men'. All too often, he found, the theories of philosophers made the primary subject matter more obscure rather than less so. The tendency of thinkers is to become bewitched by inherited philosophic

puzzles, when the persistence of the puzzle is a consequence of failing to consider the assumptions that created it. Dewey was gifted in discerning and discarding the philosophic premises that create needless mysteries. Rather than fret, for instance, about the question of how immaterial mental substance can possibly interact with material substance, he went to the root of the problem by challenging the notion of substance itself.

Indeed, Dewey's dissatisfaction with the so-called classic tradition in philosophy, stemming at least from Plato if not from Parmenides, led him to reconstruct the entire inheritance of the Western tradition in philosophy. The result is one of the most seminal and fruitful philosophies of the twentieth century.

DIALECTICAL MATERIALISM

Dialectical materialism is the official name given to Marxist-Leninist philosophy by its proponents in the Soviet Union and their affiliates elsewhere. The term, never used by either Karl Marx or Friedrich Engels, was the invention of the Russian Marxist Georgii Plekhanov, who first used it in 1891. Engels, however, favourably contrasted 'materialist dialectics' with the 'idealist dialectics' of Hegel and the German idealist tradition, and the 'dialectical' outlook of Marxism with the 'mechanistic' or 'metaphysical' standpoint of other nineteenth-century materialists.

Dialectical materialism proclaims allegiance to the methods of empirical science and opposition to all forms of scepticism which deny that science can know the nature of reality. Dialectical materialists reject religious belief generally, denying the existence of non-material or supernatural entities (such as God or an immortal human soul). Unlike other forms of materialism, however, dialectical materialists maintain that the fundamental laws governing both matter and mind are *dialectical* in the sense in which that term is used in the philosophy of G.W.F. Hegel.

Although dialectical materialism is supposed to constitute the philosophical underpinnings of Marxism, Marx's only major contribution to it was his materialist conception of history. The more fundamental philosophical views of dialectical materialism have their main source in the writings of Engels, especially *Anti-Dühring* (1878), *Dialectics of Nature* (1875–82) and *Ludwig Feuerbach and the End of Classical German Philosophy* (1886). To this last work Engels appended the eleven 'Theses on Feuerbach' written by Marx in 1845, which contrasted the 'old' or 'contemplative' materialism with the practically oriented materialism which was to be the basis of the proletarian movement. Further developments of dialectical materialism are found in writings by V.I. Lenin and subsequent Soviet writers. Lenin's chief additions were his critique of 'empirio-criticism' (the empiricist phenomenalism of certain Russian followers of Ernst Mach, who argued that matter was to be reduced to sense data), and his conception of the 'partisanship' of all philosophical views.

ALLEN W. WOOD

DIDEROT, DENIS (1713–84)

Chief editor of the great eighteenth-century *Encyclopédie* (1751–72), Diderot set out a philosophy of the arts and sciences which took the progress of civilization to be a measure of mankind's moral improvement. He did not regard that progress as having produced universal benefits, however, and perceived the Christian religion which had accompanied it as morally harmful to those who subscribed to it and even more dangerous to societies thus far untouched by it. Religious dogmas tended to pervert the organic development of human passions, and secular education which presumed that all minds were equally receptive to instruction threatened to thwart the natural evolution of human faculties in other ways.

Like Rousseau, Diderot subscribed to a philosophy of education which encouraged curiosity rather than promoted truth. He stressed the need for the adaptability of moral rules to the physiological characteristics of the individuals to whom they applied, pointing to a connection between human cultures and biology in a manner that would influence fresh outlooks upon the sciences of man at the end of the Age of Enlightenment.

DILTHEY, WILHELM (1833–1911)

Wilhelm Dilthey saw his work as contributing to a 'Critique of Historical Reason' which would expand the scope of Kant's *Critique of Pure Reason* by examining the epistemological conditions of the human sciences as well as of the natural sciences. Both kinds of science take their departure from ordinary life and experience, but whereas the

natural sciences seek to focus on the way things behave independently of human involvement, the human sciences take account of this very involvement. The natural sciences use external observation and measurement to construct an objective domain of nature that is abstracted from the fullness of lived experience. The human sciences (humanities and social sciences), by contrast, help to define what Dilthey calls the historical world. By making use of inner as well as outer experience, the human sciences preserve a more direct link with our original sense of life than do the natural sciences. Whereas the natural sciences seek explanations of nature, connecting the discrete representations of outer experience through hypothetical generalizations and causal laws, the human sciences aim at an understanding that articulates the fundamental structures of historical life given in lived experience. Finding lived experience to be inherently connected and meaningful, Dilthey opposed traditional atomistic and associationist psychologies and developed a descriptive psychology that has been recognized as anticipating phenomenology.

Dilthey first thought that this descriptive psychology could provide a neutral foundation for the other human sciences, but in his later hermeneutical writings he rejected the idea of a foundational discipline or method. Thus he ends by claiming that all the human sciences are interpretive and mutually dependent. Hermeneutically conceived, understanding is a process of interpreting the 'objectifications of life', the external expressions or manifestations of human thought and action. Interpersonal understanding is attained through these common objectifications and not, as is widely believed, through empathy. Moreover, to fully understand myself I must analyse the expressions of my life in the same way that I analyse the expressions of others.

Not every aspect of life can be captured within the respective limits of the natural and the human sciences. Dilthey's philosophy of life also leaves room for a kind of anthropological reflection whereby we attempt to do justice to the ultimate riddles of life and death. Such reflection receives its fullest expression in worldviews, which are overall perspectives on life encompassing the way we perceive and conceive the world, evaluate it aesthetically and respond to it in action. Dilthey discerned many typical worldviews in art and religion, but in Western philosophy he distinguished three recurrent types: the worldviews of naturalism, the idealism of freedom and objective idealism.

RUDOLF A. MAKKREEL

DIOGENES LAERTIUS (*c.* AD 300–50)

Diogenes Laertius is the author of a famous work entitled *Lives of the Philosophers* consisting of nearly one hundred accounts of individual philosophers. These contain mainly biographical information, but sometimes also include doctrinal summaries. The work is extremely valuable because it preserves much information on Greek philosophers from sources now lost.

DAVID T. RUNIA

DIOGENES OF SINOPE (412/403–324/321 BC)

Diogenes of Sinope was considered, along with Antisthenes, the founder of Cynicism. His nickname 'Cynic', literally 'doglike', reflects the highly unconventional lifestyle he lived and advocated. Radically re-evaluating mankind's relation to both nature and civilization, Diogenes redefined the individual's freedom and self-sufficiency, advocating a training (*askēsis*) for achieving both.

R. BRACHT BRANHAM

DISCOVERY, LOGIC OF

Bacon, Descartes, Newton and other makers of the Scientific Revolution claimed to have found and even used powerful logics or methods of discovery, step-by-step procedures for systematically generating new truths in mathematics and the natural sciences. Method of discovery was also the prime method of justification: generation by correct method was something akin to logical derivation and thus the strongest justification a claim could have. The 'logic' of these methods was deductive, inductive or both. By the mid-nineteenth century, logic of discovery was yielding to the more flexible and theory-tolerant method of hypothesis as the 'official' method of science. In the twentieth century, Karl Popper and most logical positivists completed the methodological reversal from generativism to consequentialism by setting their hypothetico-deductive method against logic of discovery. What is epistemologically important, they said, is not how new claims are generated but how they fare in empirical tests of their predictive consequences. They demoted discovery to the status of historical anecdote and psychological process. Since the late 1950s, however, there has been a revival of interest in methodology of discovery on two fronts – logical and historical. An earlier explosion of work in symbolic logic had led to automata theory, computers, and then artificial intelligence. Meanwhile, a maturing history of science was furnishing information on science as a process, on how historical actors and

communities actually discovered or constructed their claims and practices. Now, in the 1980s and 1990s, liberal epistemologists once again admit discovery as a legitimate topic for philosophy of science. Yet attempts to both naturalize and to socialize inquiry pose new challenges to the possibility of logics of discovery. Its strong associations with 'the' method of science makes logic of discovery a target of postmodernist attack, but a more flexible construal is defensible.

THOMAS NICKLES

DISCRIMINATION

A principle forbidding discrimination is widely used to criticize and prohibit actions and policies that disadvantage racial, ethnic and religious groups, women and homosexuals. Discriminatory actions often rely on unfavourable group stereotypes and the belief that members of certain groups are not worthy of equal treatment. A prohibition of discrimination applies to the distribution of important benefits such as education and jobs, and says that people are not to be awarded or denied such benefits on grounds of characteristics such as race, ethnicity, religion or gender. Attempts have been made to expand this principle to cover *institutional* discrimination. Discrimination is morally wrong because its premise that one group is less worthy than another is insulting to its victims, because it harms its victims by reducing their self-esteem and opportunities, and because it is unfair.

JAMES W. NICKEL

DODGSON, CHARLES LUTWIDGE (LEWIS CARROLL) (1832–98)

Dodgson, an Oxford teacher of mathematics, is best known under his pseudonym, Lewis Carroll. Although not an exceptional mathematician, his standing has risen somewhat in the light of recent research. He is also of note as a symbolic logician in the tradition of Boole and De Morgan, as a pioneer in the theory of voting, and as a gifted amateur photographer. His literary output, ranging from satirical pamphleteering, light verse and puzzle-making to an immense correspondence, is again largely amateur in nature, and would hardly have survived without the worldwide success of his three master-works, *Alice's Adventures in Wonderland* (1865), *Through the Looking-Glass* (1871) and *The Hunting of the Snark* (1876). Together with portions of his two-volume fairy-novel *Sylvie and Bruno* (1889/93) they are the only writings, ostensibly for children, to have attracted or deserved the notice of philosophers.

PETER HEATH

DŌGEN (1200–53)

Dōgen Kigen, the founder of Japanese Sōtō Zen Buddhism, is most noted for his argument that meditation is the expression or enactment of enlightenment, not the means to attaining it. Dōgen believed that even a novice might achieve insight, however fleeting. The difficulty, however, is in expressing that insight in one's daily acts, both linguistic and non-linguistic. In developing his position, Dōgen articulated a phenomenology of incarnate consciousness and a sophisticated analysis of meaning. His theories of mind–body unity, contextualized meaning, temporality and theory–praxis influenced many prominent modern Japanese philosophers such as Watsuji Tetsurō, Tanabe Hajime and Nishitani Keiji.

THOMAS P. KASULIS

DOSTOEVSKII, FËDOR MIKHAILOVICH (1821–81)

Dostoevskii, regarded as one of the world's greatest novelists, is especially well known for his mastery of philosophical or ideological fiction. In his works, characters espouse intriguing ideas about theology, morality and psychology. Plots are shaped by conflicts of ideas and by the interaction of theories with the psychology of the people who espouse them. Indeed, Dostoevskii is usually considered one of the greatest psychologists in the history of Western thought, not only because of the accounts of the mind his characters and narrators elucidate in detail, but also because of the peculiar behaviour betraying the depths of their souls. Dostoevskii is particularly well known for his description of the irrational in its many modes.

Deeply engaged with the political and social problems of his day, Dostoevskii brought his understanding of individual and social psychology to bear on contemporary issues and gave them a lasting relevance. His predictions about the likely consequences of influential ideas, such as communism and the social theory of crime, have proven astonishingly accurate; he has often been regarded as something of a prophet of the twentieth century.

His reputation rests primarily on four long philosophical novels – *Prestuplenie i nakazanie* (*Crime and Punishment*) (1866), *Idiot* (*The Idiot*) (1868–9), *Besy* (*The Possessed*, also known as *The*

Devils) (1871–2) and *Brat'ia Karamazovy* (*The Brothers Karamazov*) (1879–80) – and on one novella, *Zapiski iz podpol'ia* (*Notes From Underground*) (1864). In his day, Dostoevskii was as famous for his journalistic writing as for his fiction, and a few of his articles have remained classics, including 'Mr. D–bov and the Question of Art' (1861) – a critique of utilitarian aesthetics – and 'Environment' (1873).

Dostoevskii's works have had major influence on Western and Russian philosophy. In Russia, his novels inspired numerous religious thinkers, including Sergei Bulgakov and Nikolai Berdiaev; existentialists, such as Lev Shestov; and literary and ethical theorists, most notably Mikhail Bakhtin. In the West, his influence has also been great. Here, too, his writings are repeatedly cited (along with Kierkegaard's) as founding works of existentialism. Perhaps because of a misreading, they influenced Freud and Freudianism. Directly and through the medium of Bakhtin, his ideas have played a role in the rethinking of mind and language. And his rejection of utopianism and socialism has been repeatedly cited in twentieth-century political debates and theories.

Dostoevskii's influence has been diverse and at times contradictory, in part because of the different genres in which his ideas are expressed. Not only the overall meanings of his novels but also the views of his characters, including those he meant to refute, have been attributed to him. Moreover, his essays sometimes express ideas at variance with his novels. Most recently, philosophical significance has been discovered not only in the content but also in the very form of his novels. Their odd plot structure has been shown to have implications for an understanding of authorship, responsibility and time.

GARY SAUL MORSON

DOUBLE EFFECT, PRINCIPLE OF

'Double effect' refers to the good and bad effects which may foreseeably follow from one and the same act. The principle of double effect originates in Aquinas' ethics, and is supposed to guide decision about acts with double effect where the bad effect is something that must not be intended, such as the death of an innocent person. The principle permits such acts only if the bad effect is unintended, not disproportionate to the intended good effect, and unavoidable if the good effect is to be achieved. The principle has wide relevance in the moral evaluation of acts which have foreseen double effects. Controversy arises over the identification of the agent's intention in difficult cases, and over the use of the principle to resolve issues such as abortion, euthanasia, the use of pain-relieving drugs which hasten death, self-defence, and the killing of certain sorts of non-combatants in war.

SUZANNE UNIACKE

DOUBT

Doubt is often defined as a state of indecision or hesitancy with respect to accepting or rejecting a given proposition. Thus, doubt is opposed to belief. But doubt is also contrasted with certainty. Since it seems intelligible to say that there are many things we believe without being completely certain about them, it appears that we may not have a unitary concept of doubt.

Although doubt is often associated in philosophy with scepticism, historically the relation between the two is complex. Moreover, some philosophers deny that sceptical arguments have any essential connection with inducing doubts.

Sceptical doubts, as philosophers understand them, differ from ordinary doubts in their depth and generality. We all have doubts about some things. But the philosophical sceptic wonders whether we ever have the slightest reason to believe one thing rather than another. However, the reasonableness of such doubts – and even their intelligibility – remains controversial. The various attitudes philosophers adopt with respect to the status of sceptical doubts characterize the main approaches to epistemological theory.

MICHAEL WILLIAMS

DREAMING

We naturally think of dreams as experiences very like perceptions or imaginings, except that they occur during sleep. In prescientific thought the interpretation of dreams played a role in divining the future, and it plays a role, albeit a much more limited one, in modern psychology (although in Freudian psychoanalysis dreams have been considered to give access to some of the hidden operations of the mind). Dreaming is puzzling in many respects. We do not have ready-to-hand criteria for checking dream reports, not even our own; conscious or lucid dreams are the exception rather than the rule; and there is the puzzle of how we distinguish waking experience from a very lifelike dream. Furthermore, the nature of dreams is doubtful – some have even denied that to dream is to undergo an experience during sleep: dreams on

this view are to be understood in terms of what happens when we 'recall' them.

ROBERTO CASATI

DUALISM

Introduction

Dualism is the view that mental phenomena are, in some respect, nonphysical. The best-known version is that of Descartes, and holds that the mind is a nonphysical substance. Descartes argued that, because minds have no spatial properties and physical reality is essentially extended in space, minds are wholly nonphysical. Every human being is accordingly a composite of two objects: a physical body, and a nonphysical object that is that human being's mind. On a weaker version of dualism, which contemporary thinkers find more acceptable, human beings are physical substances but have mental properties, and those properties are not physical. This view is known as property dualism, or the dual-aspect theory.

Several considerations appear to support dualism. Mental phenomena are strikingly different from all others, and the idea that they are nonphysical may explain just how they are distinctive. Moreover, physical reality conforms to laws formulated in strictly mathematical terms. But, because mental phenomena such as thinking, desiring and sensing seem intractable to being described in mathematical terms, it is tempting to conclude that these phenomena are not physical. In addition, many mental states are conscious states – states that we are aware of in a way that seems to be wholly unmediated. And many would argue that, whatever the nature of mental phenomena that are not conscious, consciousness cannot be physical.

There are also, however, reasons to resist dualism. People, and other creatures with mental endowments, presumably exist wholly within the natural order, and it is generally held that all natural phenomena are built up from basic physical constituents. Dualism, however, represents the mind as uniquely standing outside this unified physical picture. There is also a difficulty about causal relations between mind and body. Mental events often cause bodily events, as when a desire causes an action, and bodily events often cause mental events, for example in perceiving. But the causal interactions into which physical events enter are governed by laws that connect physical events. So if the mental is not physical, it would be hard to understand how mental events can interact causally with bodily events. For these reasons and others, dualism is, despite various reasons advanced in its support, a theoretically uncomfortable position.

1 Mental and physical

Underlying dualism is the strong intuition that the ordinary functioning of people is of two fundamentally different kinds. Much of what happens to us is thoroughly physical, on a par with the properties and behaviour of things such as stones, houses and planets. But we also engage in thinking, we desire and perceive things, and we feel emotions such as joy and anger. In these ways we seem to be dramatically different from such purely physical objects as stones and planets. It is natural to want to epitomize these observations by positing the idea that all concrete reality is either mental or physical, and nothing is both. Not only do the mental and the physical exhaust everything; they are also mutually exclusive. This conclusion points to some form of dualism. Either every person consists of a nonphysical substance operating in tandem with a purely physical body, or people at least have certain states or properties that are not physical.

It is worth stressing that dualism requires the mental and the physical to be mutually exclusive. If they were not, mental substances might also be physical, and mental states such as thoughts and sensations might be not just mental, but also physical as well. Moreover, the common-sense contrast between mental and physical does not by itself imply that mental phenomena lie outside the physical realm. We often contrast a special range of phenomena with the physical, even though the phenomena under consideration are strictly speaking physical; consider the contrast in computer talk between physical and logical disk drives. Mental phenomena are unlike any others, but highly distinctive phenomena are not, just on that account, nonphysical.

Still, there are reasons to think that mental and physical are indeed disjoint categories. For one thing, it is held that if they were not disjoint we could not capture what it is that is distinctive about mind. If people were just physical substances, and their mental states just special sorts of physical states, we would not be able to explain the striking

difference between people and paradigmatically physical objects such as stones and houses. Some have gone so far as to urge that what is distinctive about being mental is, at bottom, simply that it is nonphysical.

But this argument is open to challenge, since we can explain the contrast between stones and people without supposing that mental and physical are mutually exclusive categories. Consider a parallel case. When we focus on living things, it is natural to contrast biological phenomena with such physical objects as stones and stars. But that does not lead us to conclude that the biological and the physical are mutually exclusive categories, and that living things are not purely physical. Rather, living organisms are physical objects, though of a very special sort, and we need not posit anything nonphysical to characterize what is special about them (see VITALISM).

Dualism implies that things are different in the case of the mind; that is, it implies that to capture what is distinctive about mental functioning we must posit substances or properties that are not physical. If, on the other hand, we can characterize the mind without positing anything nonphysical, dualism is wrong. The hypothesis that this is possible is mind–body materialism, and it has been championed especially forcefully in a version called the identity theory of mind (see MIND, IDENTITY THEORY OF).

Can such a characterization be given? According to Descartes, it is essential to everything physical that it has spatial extension, and being spatially extended implies having parts. So we can conceive of any physical object as being divided into parts; those parts would themselves be extended, and hence physical objects. But Descartes held that the same is not true about minds. Minds, he claimed, are not mere collections of mental states, as the bundle theory maintains (see MIND, BUNDLE THEORY OF); rather, minds are essentially unified. So we cannot even conceive of a mind's being divided into parts. A satisfactory characterization of the mental, therefore, implies that minds are nonphysical (see DESCARTES, R. §8).

The bundle theory put to one side, however, there is reason to question this argument. Surgically sectioning the neural pathways that connect the two cerebral hemispheres results in striking experimental behaviour, which some researchers believe indicates the presence after surgery of two distinct conscious minds. Also, brain lesions sometimes result in dissociation of mental functions, which also suggests that a normally unified mind may come to be divided. Such results cast doubt on traditional ideas about mental unity, and the very possibility of these interpretations undermines Descartes' claim that we cannot even conceive of a mind's being divided into parts. To sustain dualism, therefore, we would need some other reason to hold that a satisfactory characterization of mind must proceed in non-physical terms.

According to Descartes' well-known *cogito*, the statement 'I am, I exist' is true whenever I assert it or mentally conceive it, and the 'I' whose existence I thereby establish is my mind, not my body. But Descartes explicitly recognizes that these considerations do not constitute an argument for dualism. Rather, as he saw, they establish at best only a conceptual difference between mind and body, and not the 'Real Distinction' for which he argues independently by appeal to divisibility.

2 Dualism and physical science

To show that the mind is nonphysical, we need to know not only what being mental amounts to, but also what it is to be physical. Descartes relied on the alleged indivisibility of mind, and on a conception of the physical as divisible. That conception of physical reality, in turn, rested on Descartes' conviction that the essential properties of physical reality are all geometrical properties.

But there is another conception of physical reality that seems to support dualism. Scientific developments over the last four centuries present a picture in which the laws governing physical reality are invariably formulated in strict mathematical terms. As Galileo put it in *The Assayer*, the book of nature is 'written in the language of mathematics'.

This idea captures the mathematical character of the physical in terms that are more general than Descartes' claim that the essential properties of physical reality are all geometrical. So it allows for a less constrained argument for dualism, independently of particular claims about what is essential to the mind. Whatever the nature of thinking, sensing, desiring and feeling, one might well deny that there could be strictly mathematical laws that govern such states. On this conception of the physical, then, mental states would not be physical.

The argument as just formulated supports property dualism, according to which no mental states or properties are physical. But we can adjust the argument to support substance dualism as well. If mental substances exist, their behaviour would presumably not be governed by mathematically formulable laws; so such substances would not be physical. The argument is therefore more flexible than Descartes' appeal to indivisibility, which adapts less readily to the case of property dualism. This is important, since contemporary concern about dualism is almost always about dualism of properties, not substances. Partly that is because of doubts

about whether the traditional notion of a substance is useful. But it is also partly because of a tendency to think of people's minds not as any kind of substance at all but rather as the totality of their mental functioning, including their dispositions and abilities to function mentally.

There are various reasons to think that mental states cannot be the subjects of mathematically formulable laws. We describe our thoughts and desires in terms of the objects they are about. The property of being about something, and its related properties, are called intentional properties (see INTENTIONALITY). Mental states can be about things that do not exist; we all sometimes think about and desire nonexistent things. So thinking and desiring are somewhat like relations one can bear to nonexistent objects. But such ostensible relations, which can hold even to nonexistent things, cannot figure in mathematical descriptions of things.

There are other sorts of mental states that aren't strictly speaking about anything; examples are bodily sensations such as pains and tickles, and perceptual states such as visual experiences. The distinguishing properties of these states are not their intentional properties, but rather certain qualitative properties – for example, the redness of a visual experience or the dull, throbbing character of a pain (see QUALIA). Again, it seems unlikely that these properties could figure in mathematically formulable laws.

These intentional and qualitative properties are, arguably, the distinguishing properties of mental states – the properties in terms of which we identify those states and distinguish them from everything else. We cannot argue that mental states are physical simply by denying that they have these properties.

But our intuitive sense that these properties resist mathematical description may not be reliable. Compare our intuitions about ordinary macroscopic objects. We ordinarily take such objects to have various common-sense properties, such as colour, taste and smell. And we conceive of these common-sense physical properties in qualitative terms that seem resistant to mathematical description. Yet we can understand these properties mathematically: for example, we can construe the colours of bodies in terms of physical reflectance (see COLOUR, THEORIES OF). Perhaps, then, we can explain the intentional and qualitative properties of mental states in ways that allow for mathematical description of those properties.

The general outline such explanations would have, moreover, is clear enough. Some have argued, for example, that a thought's being about something is a matter of its having a certain content (see PROPOSITIONAL ATTITUDES), and that we can explain content, in turn, in a scientifically satisfactory way. And there is much about qualitative mental states that succumbs to quantitative treatment, as any standard textbook on perception reveals. So a successful theory of mental properties may show how to render those properties scientifically acceptable. The intuition that mental properties resist scientific treatment may therefore reflect only the current state of theorizing, just as many common-sense physical properties seemed recalcitrant to mathematical treatment before suitable scientific advances had occurred.

3 Qualitative states

Nonetheless, many would insist that, whatever science may show, qualitative properties cannot be physical. All physical objects are composed of colourless microparticles; so it is tempting to hold that no physical objects are coloured. We do, however, describe visual sensations in colour terms, for example as red or green sensations. And if nothing physical is coloured but visual sensations are, those sensations cannot be physical. Indeed, if no physical objects are coloured, colour is arguably not a physical property.

But when we describe a physical object as red, for example, this colour is a distinct property from that which we sometimes attribute to visual sensations. Physical colour is a property of a certain kind of object, namely, physical objects. Visual sensations, however, are not objects at all; they are states of people and other sentient creatures. Since the properties objects have are distinct from those of states, the colour of visual sensations is a different property from any property physical objects might have. Denying colour of physical objects does not show, therefore, that to have colour properties visual sensations must be nonphysical.

It is sometimes argued that, unless we construe sensations as objects as opposed to states, we will not be able to distinguish among the various sensations we have at any moment. And sensations are plainly not physical objects; so if they are objects of any sort, they must be nonphysical objects. But it is likely that whatever distinctions we can draw among sensations construed as objects can be preserved if we construe them as states instead.

Since bodily and perceptual sensations are not objects of any kind, but rather states of sentient creatures, there is indeed a categorial difference between sensations and physical objects. But that categorial difference is only that between objects and their states, and so by itself is irrelevant to dualism.

4 Objections to dualism

Although the character of physics underlies one major argument for dualism, a specific principle of

physics is sometimes thought to show that dualism is wrong. That principle states that in a closed physical system (that is, closed to other physical systems) the total energy remains constant. But if mental events are nonphysical, then, when mental events cause bodily events, physical motion occurs uncaused by anything physical. And this, it seems, would result in an increase of the total energy in the relevant closed physical system. Mental causation of bodily events would conflict with the principle of the conservation of energy.

No such problem arises, even if dualism is true, when bodily events cause mental events. When bodily events cause mental events, presumably they cause other physical events as well, which enables energy to be conserved. In part because this problem seems to arise only in one causal direction, some theorists have adopted a version of dualism known as epiphenomenalism, according to which mental events are nonphysical and are caused by bodily events, but are themselves causally inert (see Epiphenomenalism). Epiphenomenalism thus avoids the difficulty about conservation of energy. An even more extreme variant of dualism, known as parallelism, also avoids this difficulty, by denying that any causal interaction between mental and bodily events occurs at all. To distinguish these variants from the standard view, on which causal interaction occurs in both directions, this view is sometimes called interactionism.

But the dualist need not adopt the unintuitive idea that mental events never cause bodily events. Conservation of energy dictates only that the energy in a closed physical system is constant, not also how that energy is distributed within the system. Since mental events could effect bodily changes by altering that distribution of energy, the conservation principle does not preclude minds from having bodily effects.

A second difficulty sometimes raised also has to do with the causal interaction between the physical and the nonphysical. We seem to understand well enough how physical events cause one another, but it is held that causal interaction between mind and body is simply unintelligible, and so cannot occur. We have, it is objected, no conception whatever of how nonphysical events could cause or be caused by physical events.

But we understand how things happen only relative to a theory that governs the relevant events and tells us how those phenomena fit with various others. Understanding does not require a scientific theory; we often rely on informal, common-sense folk theories. But some theory or other is needed. So physical causation seems intelligible only because we have theories that cover those cases. And because we have no theory that governs mind–body interactions, we have no way to understand how they could occur. The appearance of unintelligibility here shows not that such interactions cannot occur, but only that we have at present no useful theory that would cover them if they do occur. Moreover, even if we cannot develop such a theory, that need not be because mind–body interaction is impossible; it might instead be due only to some limitation on our ability to understand things.

A third objection pertains again to causal interaction. For nonphysical events to cause bodily events, those nonphysical events must intervene in the normal sequence of bodily causes and effects. And it is argued that this would result in a detectable time lag somewhere in that sequence of bodily events. Because there is no such lag, dualism is mistaken. But causal intervention need not result in any relevant time lag. Consider the effects of gravitational force, the propagation of which is undetectable on the time scale relevant for brain and other bodily events. All in all, standard objections to dualism seem to fare no better than the standard arguments used to establish its truth.

5 Dualism and consciousness

Descartes defined mental states as conscious states, that is as states of which we are immediately conscious. Few today would endorse this definition, since it is generally held that mental states can and do occur without being conscious (see Unconscious mental states). But Descartes' definition fits well with dualism, because mental states provide intuitive support for dualism only when they are conscious.

Consider Descartes' argument for dualism. He held that minds are such unqualified unities that we cannot even conceive of their being divided into parts. This claim is tempting only when we focus on conscious mental states. We represent our conscious states as all belonging to a single subject, and so as inseparable from one another. But not all mental states are conscious. So this unity of consciousness does not confer a similar unity on the mind generally.

Another example concerns bodily and perceptual sensations. Dualism strikes many as most plausible for these states, because their qualitative properties seem intuitively not to be physical. But this intuition concerns only those qualitative states which are conscious. Sensations do occur of which we are in no way conscious, for example in subliminal perception or peripheral vision. And although not conscious, these sensations belong to the same types as conscious sensations; we subliminally sense various standard colours, for example, and

sounds of various types. Since we distinguish types of sensation by their qualitative properties, the nonconscious sensations that occur in subliminal perception must have the same distinguishing properties as conscious sensations have, namely qualitative properties. The only difference is that in these cases we are in no way conscious of being in states that have those properties.

But when sensations are not conscious, there is no reason to think they resist being described in terms appropriate for the physical sciences. And the same holds for mental states of whatever sort, when they are not conscious. Dualism is intuitively plausible only for conscious mental states.

Considerations raised in the previous section also help disarm this last argument. Our failure to understand how neural processes could have qualitative properties reflects only our lack of a suitable theory of how neural processes could have such properties; it does not show that they do not have those properties.

Consider a related argument. We have, it seems, no conception of how bodily states could have the qualitative properties in terms of which we characterize sensations. It seems simply unintelligible that neural occurrences, or any other physical events, could have the qualities exhibited by a conscious sensation of pain, or a conscious experience of seeing red. This has led some to argue that qualitative mental states cannot be physical. But, again, the argument has force only for conscious states. When qualitative states are not conscious, we have no intuitive problem understanding how their distinguishing properties could belong to physical states.

Consciousness is presupposed even in empirical arguments for dualism. Libet, for example, has experimentally isolated certain anomalies about the subjective timing of mental events, which he thinks suggest causal intervention by nonphysical factors. But these anomalies are detectable only when subjects report their mental states, and thus only when those states are conscious. In addition, a mental state's being conscious consists in a subject's being conscious of that state in a way that seems immediate. So anomalies about subjective timing may be due not to intervention by nonphysical causes, but to differences between when mental events occur and when subjects become conscious of them.

Evidently dualism derives no support from mental states that are not conscious. But then it is unclear why cases in which we are conscious of our mental states should make dualism more plausible.

One reason sometimes offered is the subjective differences among conscious experiences, which seem to resist treatment in physicalist terms. But these differences can very likely be explained by appeal to differences in the circumstances and perceptual apparatus of various sentient creatures. Once it is clear that nonconscious mental states lend no plausibility to dualism, it is unlikely that conscious states will either (see Consciousness).

6 Dualism and the concept of mind

Because dualism conflicts with the scientific consensus that at bottom everything is physical, it receives little endorsement today. But among those who reject dualism, there are some who nonetheless find compelling certain reasons for holding that mental phenomena are nonphysical. They deny, for example, that the distinguishing properties of thoughts and sensations can be construed so as to conform to the dictates of physicalist description, or they have some other reason to hold that mental phenomena are nonphysical. They combine a dualist conception of what mental states are with a rejection of dualism.

The only option for such theorists is to deny that anything mental exists. This denial, known as eliminative materialism, adopts a traditional, dualist concept of mind, but insists that this dualist conception does not apply to anything. Though certain nonmental, physical phenomena may enable us to explain and predict things we usually explain and predict by appeal to mental states, on this view nothing mental exists (see Eliminativism).

Because eliminativism relies on a dualist concept of mind, we can very likely avoid this extravagant result. As argued above, we need not construe mental states and their properties in ways that imply the dualist claim that mental phenomena are nonphysical. Accordingly, we can resist both dualism and the eliminativist alternative.

DUHEM, PIERRE MAURICE MARIE (1861–1916)

Duhem was a French Catholic physicist, historian of science and philosopher of science. Champion of a programme of generalized thermodynamics as a unifying framework for physical science, he was a pioneer in the history of medieval and Renaissance science, where he emphasized a continuity between medieval and early modern science. Duhem was also one of the most influential philosophers of science of his day, thanks to his opposition to mechanistic modes of explanation and his development of a holistic conception of scientific theories, according to which individual empirical propositions are not tested in isolation but only in conjunction with other theoretical claims and associated auxiliary hypotheses. Such a view of theory testing entails that there are no 'crucial experiments' deciding unambiguously for or against a given theory and that empirical evidence therefore underdetermines theory choice. Theory choice is thus partly a matter of convention. Duhem's conventionalism is similar in kind to that later advocated by Otto Neurath and by W.V. Quine.

DUMMETT, MICHAEL ANTHONY EARDLEY (1925–)

For Michael Dummett, the core of philosophy lies in the theory of meaning. His exploration of meaning begins with the model proposed by Gottlob Frege, of whose work Dummett is a prime expositor. A central feature of that model is that the sense (content) of a sentence is given by a condition for its truth, displayed as deriving from its constituent structure. If sense so explicated is to explain linguistic practice, knowledge of these truth-conditions must be attributed to language users by identifying features of use in which it is manifested. Analysis of truth suggests we seek such manifestation in patterns of assertion. But scrutiny of those patterns shows that there is no distinction between use which manifests knowledge of classical truth-conditions, and use which manifests knowledge of a weaker kind of truth – for example, one which holds whenever we possess a potential warrant for a statement.

Such considerations motivate reconstruing sense as given by conditions for this weaker kind of truth. But rejigging Fregean semantics in line with such a conception is highly nontrivial. Mathematical intuitionism, properly construed, gives us models for doing so with mathematical language; Dummett's programme is to extend such work to everyday discourses. Since he further argues that realism consists in defending the classical semantics for a discourse, this programme amounts to probing the viability of antirealism about such things as the material world, other minds and past events.

BARRY TAYLOR

DUNS SCOTUS, JOHN (*c.*1266–1308)

Duns Scotus was one of the most important thinkers of the entire scholastic period. Of Scottish origin, he was a member of the Franciscan order and undertook theological studies first at Oxford and later at Paris. He left behind a considerable body of work, much of which unfortunately was still undergoing revision at the time of his death. Notable among his works are questions on Aristotle's *Metaphysics*, at least three different commentaries on the *Sentences* of Peter Lombard (the required text for a degree in theology) and a lengthy set of university disputations, the quodlibetal questions. A notoriously difficult and highly original thinker, Scotus was referred to as 'the subtle doctor' because of his extremely nuanced and technical reasoning. On many important issues, Scotus developed his positions in critical reaction to the Parisian theologian Henry of Ghent, the most important thinker of the immediately preceding generation and a severe Augustinian critic of Aquinas.

Scotus made important and influential contributions in metaphysics, epistemology and ethics. In metaphysics, he was the first scholastic to hold that the concepts of being and the other transcendentals were univocal, not only in application to substance and accidents but even to God and creatures. In this, Scotus broke with the unanimous view based on Aristotle that being could not be predicated of both substance and accident, much less of, except by analogy, God and creature. Scotus argued in general that univocity was required to underwrite any natural knowledge of God from creatures or of substance from accidents. Given univocity, he concluded that the primary object of the created intellect was being, rejecting Aquinas' Aristotelian view that it was limited to the quiddity of the sense particular and Henry of Ghent's Augustinian view

that it was God. That is, Scotus argues that even the finite intellect of the creature is by its very nature open to knowing all being.

Scotus' proof of the existence of God is the most ambitious of the entire scholastic period. Prior efforts at demonstrating the existence of God showed little concern with connecting the eclectic body of inherited arguments. Scotus' proof stands apart as an attempt to integrate logically into a single demonstration the various lines of traditional argument, culminating in the existence of God as an actually infinite being. As a result, his demonstration is exceedingly complex, establishing within a sustained and protracted argument God as first efficient cause, as ultimate final cause and as most eminent being – the so-called triple primacy – the identity within a unique nature of these primacies, and finally the actual infinity of this primary nature. Only with this final result of infinity is Scotus prepared to claim he has fully demonstrated the existence of God. Notable features of the proof include Scotus' rejection of Aristotle's argument from *Physics* VIII (the favoured demonstration of Aquinas), the reduction of exemplar cause to a species of efficient cause, important clarifications about the causal relations at issue in arguments against infinite regress, an a priori proof constructed from the possibility of God similar to that proposed by Leibniz, and the rejection of the traditional argument that the infinity of God can be inferred from creation *ex nihilo*.

Scotus is a realist on the issue of universals and one of the main adversaries of Ockham's programme of nominalism. He endorsed Avicenna's theory of the common nature, according to which essences have an independence and priority to their existence as either universal in the mind or singular outside it. Intepreting Avicenna, Scotus argued that natures as common must have their own proper unity which is both real and less than the numerical unity of a singular; that is, natures are common prior to any act of the intellect and possess their own real, lesser unity. They are accordingly not of themselves singular, but require a principle of individuation. Rejecting the standard views that essences are individuated by either actual existence, quantity or matter, Scotus maintained that the principle of individuation is a further substantial difference added to the species. This 'individual difference' is the so-called *haecceitas* or 'thisness', a term used seldom by Scotus himself. The common nature and individual difference were said by Scotus to be really identical in the individual, but 'formally distinct'. The 'formal distinction,' developed by Scotus chiefly in connection with the Trinity and the divine attributes, is an integral part of his realism and was as such attacked by Ockham. It admits within one and the same thing a distinction between realities, formalities or entities antecedent to any act of the intellect to provide an objective foundation for our concepts. These formalities are nonetheless really identical and inseparably united within the individual.

In epistemology, Scotus is important for his demolition of Augustinian illumination, at least in the elaborate defence of it given by Henry of Ghent, and the distinction between intuitive and abstractive cognition. Scotus rejected Henry's defence as leading to nothing but scepticism, and set about giving a complete account of certitude apart from illumination. He grounded certitude in the knowledge of self-evident propositions, induction and awareness of our own states. After Scotus, illumination never made a serious recovery. Scotus' other epistemological contribution was the allocation to the intellect of a direct, existential awareness of the intelligible object. This was called intuitive cognition, in contrast to abstractive knowledge, which seized the object independently of whether it was present to the intellect in actual existence or not. This distinction, credited to Scotus by his contemporaries, was invoked in nearly every subsequent scholastic discussion of certitude.

While known primarily for his metaphysics, the importance and originality of Scotus' ethical theory has been increasingly appreciated. Scotus is a voluntarist, holding for example that not all of the natural law (the decalogue) is absolutely binding, that prudence and the moral virtues are not necessarily connected and that the will can act against a completely correct judgment of the intellect. It is Scotus' theory of will itself, however, that has attracted the most attention. He argues that the will is a power for opposites, not just in the sense that it can have opposite acts over time but in the deeper sense that, even when actually willing one thing, it retains a real, active power to will the opposite. In other words, he detaches the notion of freedom from those of time and variability, arguing that if a created will existed only for an instant its choice would still be free. In this, he has been heralded as breaking with ancient notions of modality that treated contingency principally in terms of change over time. Scotus argued that the will, as a capacity for opposites, was the only truly rational power, where the rational was opposed to purely natural agents whose action was determined. In this sense, the intellect, as a purely natural agent, was not a rational power. Finally, Scotus endowed the will with an innate inclination to the good in itself apart from any advantage it might bring to the agent. This inclination or affection for the just (*affectio iustitiae*, as it was termed by Anselm), enabled the will to escape the deterministic

inclination of natures toward their own perfection and fulfilment.

DUTY

See Kantian ethics

DUTY AND VIRTUE, INDIAN CONCEPTIONS OF

Two principal strains of ethical thought are evident in Indian religious and philosophical literature: one, central to Hinduism, emphasizes adherence to the established norms of ancient Indian culture, which are stated in the literature known as the Dharma-śāstras; another, found in texts of Buddhism, Jainism and Hinduism alike, stresses the renunciation of one's familial and social obligations for the sake of attaining enlightenment or liberation from the cycle of rebirth. The Dharmaśāstras define in elaborate detail a way of life based on a division of society into four 'orders' (*varṇas*) – priests, warriors, tradesmen and servants or labourers – and, for the three highest orders, four 'stages of life' (*āśramas*). Renunciation is valid only in the final two stages of life, after one has fulfilled one's responsibilities as a student of scripture and as a householder. The various traditions that stress liberation, on the other hand, advocate total, immediate commitment to the goal of liberation, for which the householder life presents insuperable distractions. Here, the duties of the householder are replaced by the practice of yoga and asceticism. Nevertheless, specific ethical observances are also recommended as prerequisites for the achievement of higher knowledge through yoga, in particular, nonviolence, truthfulness, not stealing, celibacy and poverty. The liberation traditions criticized the system of the Dharmaśāstras for being overly concerned with ritual and external forms of purity and condoning – indeed, prescribing – the killing of living beings in Vedic sacrifices; but it was only in the Dharmaśāstras that the notion of action solely for duty's sake was appreciated. The Hindu scripture the *Bhagavad Gītā* (Song of God) represents an effort to synthesize the two ideals of renunciation and the fulfilment of obligation. It teaches that one should integrate yoga and action in the world. Only when acting out of the state of inner peace and detachment that is the culmination of the practice of yoga can one execute one's duty without regard for the consequences of one's actions. On the other hand, without the cultivation of inner yoga, the external forms of renunciation – celibacy, mendicancy, asceticism – are without significance. It is inner yoga that is the essence of renunciation, yet yoga is quite compatible with carrying out one's obligations in the world.

JOHN A. TABER

DWORKIN, RONALD (1931–)

Ronald Dworkin's early, highly controversial, thesis that there are right answers in hard cases in law, coupled with his attack on the idea that law is simply a system of rules, gained him a prominent and distinct place in the anti-positivist strand of legal theory. He has developed and enriched his earlier insights by tying his notion of law-as-interpretation to the ideals of community and equality. Dworkin is an influential representative of liberal thought, who combines clear and analytical thinking with political involvement expressed in decisive and timely interventions in many of the important political debates of our time.

EARLY CHRISTIAN PHILOSOPHY

See PATRISTIC PHILOSOPHY

EAST ASIAN PHILOSOPHY

Sinitic civilization, which includes the Chinese-influenced cultures of Japan and Korea, established an early lead over the rest of the world in the development of its material culture – textiles, iron casting, paper, maritime arts, pottery, soil sciences, agricultural and water technologies, and so on. For centuries after the first sustained incursions of Europe into East Asia, there were more books printed in the classical Chinese language – the 'Latin' of East Asia – than in all of the rest of the world's languages combined. As recently as the beginning of the industrial revolution in the eighteenth century, it was China rather than Europe which, by most standards, was the arbiter of science and civilization on this planet.

If 'philosophy' – the pursuit of wisdom – is an aspiration of high cultures generally, why then was it not until the late nineteenth century, in response to a growing relationship with Western learning, that an East Asian term for 'philosophy' was coined, first by the Japanese (*tetsugaku*), and then introduced into Chinese (*zhexue*) and Korean (*ch'ôlhak*)? If it would be absurd to suggest that East Asian cultures have no history, no sociology, no economics, then how do we explain the fact that Asian philosophy is a subject neither researched nor taught in most Anglo-European seats of higher learning?

1 Uncommon assumptions, common misconceptions

The prominent French sinologist Jacques Gernet (1985) argues that when the two civilizations of China and Europe, having developed almost entirely independently of each other, first made contact in about 1600, the seeming resistance of the Chinese to embracing Christianity and, more importantly, the philosophic edifice that undergirded it was not simply an uneasy difference in the encounter between disparate intellectual traditions. It was a far more profound difference in mental categories and modes of thought, and particularly, a fundamental difference in the conception of human agency. Much of what Christianity and Western philosophy had to say to the East Asians was, quite literally, nonsense – given their own philosophic commitments, they could not think it. In turn, the Jesuits interpreted this difference in ways of thinking quite specifically as ineptness in reasoning, logic and dialectic.

The West has fared little better in its opportunity to appreciate and to appropriate Sinitic culture. In fact, it has fared so badly that the very word 'Chinese' in the English language, found in illustrative expressions from 'Chinese revenge' and 'Chinese puzzle' to 'Chinese firedrill', came to denote 'confusion', 'incomprehensibility' or 'impenetrability', a sense of order inaccessible to the Western mind. The degree of difference between a dominant Western metaphysical sense of order and the historicist 'aesthetic' order prevalent in the radial Sinitic worldview has plagued the encounter between these antique cultures from the start. When seventeenth-century European savants such as LEIBNIZ and WOLFF were looking to corroborate their universal indices in other high cultures – the one true God, impersonal rationality, a universal language – China was idealized as a remarkable and 'curious land' requiring the utmost scrutiny. In the course of time, however, reported on by philosophers such as KANT, HEGEL, MILL and EMERSON, Western esteem for this 'curious

land' plummeted from such 'Cathay' idealizations to the depths of disaffection for the inertia of what, in the context of the Europe-driven Industrial Revolution, was recast as a moribund, backward-looking and fundamentally stagnant culture.

In classical Chinese there is an expression: 'We cannot see the true face of Mount Lu because we are standing on top of it.' Although virtually all cultural traditions and historical epochs are complex and diverse, there are certain fundamental and often unannounced assumptions on which they stand that give them their specific genetic identity and continuities. These assumptions, extraordinarily important as they are for understanding the cultural narrative, are often concealed from the consciousness of the participants in the culture who are inscribed by them, and become obvious only from a perspective external to the particular tradition or epoch. Often a tradition suspends within itself competing and even conflicting elements which, although at odds with one another, still reflect a pattern of importances integral to and constitutive of its cultural identity. These underlying strands are not necessarily or even typically logically coherent or systematic, yet they do have a coherence as the defining fabric of a specific and unique culture.

Looking at and trying to understand elements of the East Asian cultural narrative from the distance of Western traditions, then, embedded as we are within our own pattern of cultural assumptions, has both advantages and disadvantages. One disadvantage is obvious and inescapable. To the extent that we are unconscious of the difference between our own fundamental assumptions and those that have shaped the emergence of East Asian philosophies, we are sure to impose upon this geographical area our own presuppositions about the nature of the world, making what is exotic familiar and what is distant near. On the other hand, a clear advantage of an external perspective is that we are able to see with greater clarity at least some aspects of 'the true face of Mount Lu': we are able to discern, however imperfectly, the common ground on which the Confucian and the Buddhist stand in debating their differences, ground which is in important measure concealed from they themselves by their unconscious assumptions.

2 One-world natural cosmology

In the dominant world view of classical East Asia, we do not begin from the dualistic 'two-world' reality/appearance distinction familiar in classical Greek metaphysics, giving rise as it does to ontological questions such as: 'What is the Being behind the beings?' Rather, we begin from the assumption that there is only the one continuous concrete world that is the source and locus of all of our experience, giving rise to cosmological and ultimately ethical questions such as: 'How do these myriad beings best hang together?' Order within the classical East Asian world view is 'immanental' and 'emergent', an indwelling regularity in things themselves. It is the always unique yet continuous graining in wood, the distinctive striations in a piece of jade, the regular cadence of the surf, the peculiar veining in each and every leaf. The power of creativity resides in the world itself. The order and regularity this world evidences is neither derived from nor imposed upon it by some independent, activating power, but inheres in the world itself. Change and continuity are equally 'real'; time itself is the persistence of this self-transformation.

The 'one' world, then, is the efficient cause of itself. Situation takes priority over agency; process and change take priority over form and stasis. The context itself is resolutely dynamic, autogenerative, self-organizing and, in a real sense, alive. This one world is constituted as a sea of *qi*, psychophysical energy that disposes itself in various concentrations, configurations and perturbations. There is an intelligible pattern that can be discerned and mapped from each different perspective within the world that is its *dao*, a 'pathway' which can, in varying degrees, be traced out to make one's place and one's context coherent. *Dao* is, at any given time, both *what* the world is and *how* it is, always as entertained from some particular perspective or another. In this tradition, there is no final distinction between some independent source of order, and what it orders. There is no determinative beginning or presumptive teleological end. The world and its order at any particular time is self-causing, 'so-of-itself' (*ziran*) (see Chinese philosophy; Daoist philosophy). Truth, beauty and goodness as standards of order are not 'givens': they are historically emergent, something done, a cultural product. Given the priority of situation over agency, there is a continuity between nature and nurture, a mutuality between context and the human being. In such a world, it is not unexpected that the *Yijing* (Book of Changes) is the first among the ancient classics.

3 Ars contextualis*: the art of contextualizing*

The 'two-world' metaphysical order inherited out of classical Greece has given the Western tradition a theoretical basis for *objectivity* – the possibility of standing outside and taking a wholly external view of things – a 'view from nowhere'. Objectivity is not only the basis for such universalistic claims as objective truth, impersonal reason and necessity, but further permits the decontextualization of things as 'objects' in our world. It is the basis on which we

can separate objective description from subjective prescription.

By contrast, in the 'one world' of classical East Asia, instead of starting abstractly from some underlying, unifying and originating principle, one begins from one's own specific place within the world. Without objectivity, 'objects' dissolve into the flux and flow, and existence becomes a continuous, uninterrupted process. Each person is invariably experiencing the world as one perspective within the context of many. Since there is only the one world, we cannot get outside of it. From the always unique place one occupies within the cosmos of classical East Asia, one construes and interprets the order of the world around one as contrasting 'thises' and 'thats'– 'this person' and 'that person' – more or less proximate to oneself. Since each and every person or thing or event is perceived from some position or other, and hence is continuous with the position that entertains it, each thing is related to and a condition of every other.

In the human world, all relationships are continuous from ruler and subject to friend and friend, relating everyone as an extended 'family'. Similarly, all 'things', like all members of a family, are correlated and thus interdependent. Every thing is holographic in entailing all other things as conditions for its continued existence, and is what it is at the pleasure of everything else. Whatever can be predicated of one thing or one person is a function of a network of relationships, all of which combine to give it its role and to constitute its place and its definition.

There is no strict notion of identity that issues forth as some essential defining feature – a divinely endowed soul, rational capacity or natural locus of rights – that makes all human beings equal. In the absence of such equality, the various relationships which define one thing in relation to another are qualitatively hierarchical and contrastive: bigger or smaller, more noble or more base, harder or softer, stronger or weaker, more senior or more junior. Change in the quality of relationships between things always occurs on a continuum as movement between such polar oppositions.

The general and most basic language for articulating such correlations among things is metaphorical: in some particular aspect at some specific point in time, one person or thing is 'overshadowed' by another; that is, made *yin* to another's *yang*. Literally, *yin* means 'shady' and *yang* means 'sunny', defining in the most general terms those contrasting and hierarchical relationships which constitute indwelling order and regularity.

It is important to recognize the *interdependence* and correlative character of the *yin–yang* kind of polar opposites, and to distinguish this contrastive tension from the dualistic opposition implicit in the vocabulary of the classical Greek world, where one primary member of a set such as Being transcends and stands *independent* of, and thus is more 'real' than, the world of Becoming. The implications of this difference between dualism and correlativity contrast are fundamental and pervasive.

To continue the 'person' example, generally in East Asian philosophy, a particular person is not a discrete individual defined in terms of some inherent nature, but is a centre of constitutive roles and relationships. These roles and relationships are dynamic, constantly being enacted, reinforced and ideally deepened through the multiple levels of natural, cultural and social discourse. By virtue of these specific roles and relationships, a person comes to occupy a place and posture in the context of family, community and world. The human being is not shaped by some given design which underlies natural and moral order in the cosmos, and which stands as the ultimate objective of human growth and experience. Rather, the 'purpose' of the human experience, if it can be so described, is more immediate; it is to coordinate the various ingredients which constitute one's particular world here and now, and to negotiate the most productive harmony out of them. Simply put, it is to get the most out of what you have here and now.

4 Radial harmony

A major theme in Confucianism, foundational throughout East Asia, is captured in the phrase from *Analects* 13.23, 'the exemplary person pursues harmony (*ho*), not sameness' (see CONFUCIAN PHILOSOPHY, CHINESE). This conception of 'harmony' is explained in the classical commentaries by appeal to the culinary arts. In the classical period, a common food staple throughout northern Asia was *keng*, a kind of a millet gruel in which various locally available and seasonal ingredients were brought into relationship with one another. The goal was for each ingredient – the cabbage, the radish, the bit of pork – to retain its own colour, texture and flavor, but at the same time to be enhanced by its relationship with the other ingredients. The key to this sense of harmony is that it begins from the unique conditions of a specific geographical location and the full contribution of those particular ingredients readily at hand – *this* piece of cabbage, *this* fresh, young radish, *this* tender bit of pork and so on – and relies upon artistry rather than recipe for its success.

The Confucian distinction between an inclusive harmony and an exclusive sameness has an obvious social and political application, underscoring the fertility of the kind of harmony that maximizes

difference. This 'harmony' is not a given in some preassigned cosmic design, but is the quality of the combination at any one moment created by effectively correlating and contextualizing the available ingredients, whether they be foodstuffs, farmers or infantry. It is not a quest of discovery, grasping an unchanging reality behind the shadows of appearance, but a profoundly creative journey where the quality of the journey is itself the end. It is the attempt to make the most of any situation.

In summary, at the core of the classical East Asian worldview is the cultivation of radial harmony, a specifically 'centre-seeking' or 'centripetal' harmony which is productive of consensus and orthodoxy. This harmony begins from what is most concrete and immediate – that is, from the perspective of any particular human being – and draws through patterns of deference from the outside in toward its centre. Hence there is the almost pervasive emphasis on personal cultivation and refinement as the starting point for familial, social, political and cosmic order. A preoccupation in classical East Asian philosophy, then, is the cultivation of this centripetal harmony as it begins with oneself, and radiates outward.

The East Asian world view is thus dominated by this 'bottom-up' and emergent sense of order which begins from the coordination of concrete detail. It can be described fairly as an 'aestheticism', exhibiting concern for the artful way in which particular things can be correlated efficaciously to thereby constitute the *ethos* or character of concrete historical events and cultural achievements. Order, like a work of art, begins with always unique details, from 'this bit' and 'that', and emerges out of the way in which these details are juxtaposed and harmonized. As such, the order is embedded and concrete – the colouration that differentiates the various layers of earth, the symphony of the morning garden, the wind piping through the orifices of the earth, the rituals and roles that constitute a communal grammar to give community meaning. Such an achieved harmony is always particular and specific, and is resistant to notions of formula and replication.

5 Philosophical syncreticism

As one might expect in a cultural narrative which privileges interdependence and the pursuit of radial harmony, orthodoxy is neither exclusive nor systematic. Rather, traditions are porous and syncretic. In the Han dynasty, for example, Confucianism is first fortified by elements appropriated from the competing schools of pre-Qin China such as Daoism and Legalism. Later it absorbs into itself an increasingly Sinicized Buddhist tradition, evolving over time into a neo-Confucianism. At the same time, the *shuyuan* acadamies established by the great neo-Confucian syncretist Zhu Xi are modelled on Buddhist monastic schools. In more recent years the Western heresy, Marxism, and other elements of Western learning such as the philosophy of KANT and HEGEL, are being appropriated by China and digested to produce what today is being called the 'New Confucianism' (see MARXISM, WESTERN).

The indigenous shamanistic tradition of Korean popular religion absorbed first Buddhism and then Confucianism from China, reshaping these traditions fundamentally to suit the uniqueness of the Korean social and political conditions (see BUDDHIST PHILOSOPHY, KOREAN). Native Japanese Shintoism emerges as a distinction made necessary by the introduction of first Buddhism and then Confucianism, where each tradition assumes a complementary function within the culture (see SHINTŌ; BUDDHIST PHILOSOPHY, JAPANESE). More recently, in the work of Kyoto School thinkers such as NISHIDA, TANABE and Nishitani, German idealism is mined and alloyed with the Japanese Buddhist tradition to produce new directions.

Although Confucianism, Buddhism and Daoism – the dominant traditions of East Asia – have certainly been rivals at one level, it has been characteristic of the living philosophical traditions defining of East Asian culture to pursue mutual accommodation through an ongoing process of encounter and appropriation; hence the familiar expression *sanjiao weiyi*, 'the three teachings (Confucianism, Buddhism and Daoism) are as one'. A continuation of this process is presently underway with the ongoing East Asian appropriation of Western philosophy.

ECLECTICISM

Eclecticism in philosophy is the construction of a system of thought by combining elements of the established systems of a previous age. The term ‘eclecticism’ is derived from the Greek verb *eklegein/eklegesthai*: to pick out, choose, or select. Diogenes Laertius (*c.* AD 300–50) attributes an ‘eclectic school’ to Potamo of Alexandria (*c.* early 3rd century AD) ‘who made a selection from the tenets of all the existing sects’. Many philosophers of the Greco-Roman period are known as ‘eclectics’, and one can find the entire period of philosophy from the second century BC to the third century AD referred to as an age of ‘eclecticism’. In such cases the term is often used pejoratively to designate a discordant collection of unoriginal ideas. More recently, however, the French philosopher Victor Cousin (1792–1867) expressed an optimistic view of eclecticism while using the term in reference to his own philosophy. Cousin viewed the entire history of thought as dominated by the two competing philosophies of empiricism (or sensualism) and idealism (or rationalism). The true philosophy would eliminate conflicting elements and combine the remaining truths within a single, unified system. Cousin’s eclecticism, with its strong historical orientation, was the predominant school of thought in France throughout most of the nineteenth century and was also of considerable influence in Brazil.

ECOLOGICAL PHILOSOPHY

In the early 1970s a small number of academic philosophers in the English-speaking world began to turn their attention to questions concerning the natural environment. Environmental philosophy initially encompassed various types of inquiry, including applied ethics oriented to issues such as nuclear power and the deployment of toxic chemicals; more abstract extrapolations of traditional ethical theories, such as Kantianism and utilitarianism, into environmental contexts; and, also, a far more radical project involving the reappraisal of basic presuppositions of Western thought in the light of their implications for our relation to the natural world. The first two were basically extensions of existing areas of philosophy, and it is arguably the third project – often described as ‘ecological philosophy’ or ‘ecophilosophy’ – which constitutes a distinctively new branch of philosophy.

Although the ecophilosophical project was explicitly normative in intent, it was quickly found to entail far-reaching investigations into the fundamental nature of the world. Indeed it was seen by many as entailing a search for an entirely new ecological paradigm – a worldview organized around a principle of interconnectedness, with transformative implications for metaphysics, epistemology, spirituality and politics, as well as ethics. Moreover, the process of elaborating a new ecological view of the world was found to uncover the contours of an already deeply embedded worldview, organized around a principle of separation or division, underlying and shaping the traditional streams of modern Western thought.

FREYA MATHEWS

ECONOMICS AND ETHICS

Unlike many other sciences, economics is linked both to ethics and to the theory of rationality. Although many economists regard economics as a ‘positive’ science of one sort of social phenomena, economics is built around a normative theory of rationality, and has a special relevance to policy making and the criticism of social institutions. Economics complements and intersects with moral philosophy in both the concepts it has constructed and in its treatment of normative problems.

Fundamental to modern economics is its conception of human beings as rational agents, whose choices are determined by complete and transitive preferences. Although economists stress the usefulness of this notion of rationality in explaining human behaviour, rationality is clearly also a normative notion. The mathematical tools economists have developed to represent and study the implications of rational action in collective and interactive contexts are thus of immediate relevance to moral philosophers.

Also of interest to moral philosophy is the problematic attempt in welfare economics to fashion a normative theory of economic institutions and policies around the goal of helping people satisfy their subjective preferences. This project relies, controversially, on equating people’s well-being with the degree of satisfaction of their subjective preferences; an individual’s ‘utility’ on this view is no more than an index of how well their subjective preferences are satisfied. Furthermore, since most welfare economists assume that there is no meaningful way to compare degrees of

preference satisfaction across people, the project also requires a scheme for weighing the effectiveness of alternative economic arrangements in satisfying preferences without weighing the comparative satisfaction levels of different individuals. Central to the project is Pareto optimality – the notion of an 'efficient' arrangement as one in which no individual can achieve higher preference satisfaction without someone else undergoing a reduction in their satisfaction level.

Economic policies and institutions can be appraised in terms of a variety of values other than efficiency. Notable both in historical and contemporary discussions are the values of liberty, justice and equality. Since a large part of economics is carried out with a view to its possible application to policy, ethics has a significant part to play in economics. By the same token, economics may be of great importance to ethics, both through its exploration of consequences and through the development of mathematical and conceptual tools.

EDUCATION, PHILOSOPHY OF

The philosophy of education is primarily concerned with the nature, aims and means of education, and also with the character and structure of educational theory, and its own place in that structure. Educational theory is best regarded as a kind of practical theory which would ideally furnish useful guidance for every aspect and office of educational practice. Such guidance would rest in a well-grounded and elaborated account of educational aims and the moral and political dimensions of education, and also in adequate conceptions and knowledge of teaching, learning, evaluation, the structure and dynamics of educational and social systems, the roles of relevant stake-holders and the like.

Philosophers of education often approach educational issues from the vantage points of other philosophical sub-disciplines, and contribute in a variety of ways to the larger unfinished project of educational theory. These contributions may be divided into work on the nature and aims of education, on the normative dimensions of the methods and circumstances of education, and on the conceptual and methodological underpinnings of its methods and circumstances – either directly or through work on the foundations of other forms of research relied upon by education theory.

Philosophical analysis and argument have suggested certain aims as essential to education, and various movements and branches of philosophy, from Marxism and existentialism to epistemology and ethics, have suggested aims, in every case controversially. Thus, one encounters normative theories of thought, conduct and the aims of education inspired by a broad consideration of epistemology, logic, aesthetics and ethics, as well as Marxism, feminism and a host of other '-isms'. In this mode of educational philosophizing, the objects of various branches of philosophical study are proposed as the ends of education, and the significance of pursuing those ends is elaborated with reference to those branches of study.

A second form of educational philosophy derives from substantive arguments and theories of ethics, social and political philosophy and philosophy of law, and concerns itself with the aims of education and the acceptability of various means to achieve them. It revolves around arguments concerning the moral, social and political appropriateness of educational aims, initiatives and policies, and moral evaluation of the methods, circumstances and effects of education. Recent debate has been dominated by concerns about children's rights and freedom, educational equality and justice, moral and political education, and issues of authority, control and professional ethics.

The philosophy of education has also sought to guide educational practice through examining its assumptions about the structure of specific knowledge domains and the minds of learners; about learning, development, motivation, and the communication and acquisition of knowledge and understanding. Philosophy of science and mathematics have informed the design of curriculum, pedagogy and evaluation in the teaching of science and mathematics. Philosophy of mind, language and psychology bear on the foundations of our understanding of how learning occurs, and thus how teaching may best promote it.

RANDALL R. CURREN

EDWARDS, JONATHAN (1703–58)

Jonathan Edwards' work as a whole is an elaboration of two themes – God's absolute sovereignty and the beauty of his holiness. God's sovereignty is articulated in several ways. *Freedom of the Will* (1754) defends theological determinism. God is the complete cause of everything that occurs, including human volitions. Edwards is also an occasionalist, idealist and mental phenomenalist. God is the only real cause of events. Human volitions and 'natural causes' are mere 'occasions' upon which God produces the appropriate effects. Physical objects are collections of sensible 'ideas' of colour, shape, solidity, and so on, and finite minds are collections

of 'thoughts' or 'perceptions'. God's production of sensible ideas and thoughts in the order which pleases him is the only 'substance' underlying them. God is thus truly 'being in general', the 'sum of all being'.

The beauty or splendour of God's holiness is the principal theme of two late works – *End of Creation* and *True Virtue* (both published posthumously in 1765). The first argues that God's end in creation is the external manifestation of his internal splendour. That splendour primarily consists in his holiness and its most perfect external expression is the holiness of the saints, which mirrors and depends upon it. *True Virtue* defines holiness as 'true benevolence' or 'the love of being in general', and distinguishes it from such counterfeits as rational self-love, instincts like parental affection and pity, and natural conscience. Since beauty is defined as 'agreement' or 'consent' and since true benevolence consents to being in general, true benevolence alone is truly beautiful. Natural beauty and the beauty of art are merely its image. Only those with truly benevolent hearts, however, can discern this beauty.

Edwards' projected *History of Redemption* would have drawn these themes together, for it is in God's work of redemption that his sovereignty, holiness and beauty are most effectively displayed.

WILLIAM J. WAINWRIGHT

EGOISM AND ALTRUISM

Introduction

Henry Sidgwick conceived of egoism as an ethical theory parallel to utilitarianism: the utilitarian holds that one should maximize the good of all beings in the universe; the egoist holds instead that the good one is ultimately to aim at is only one's own. This form of egoism (often called 'ethical egoism') is to be distinguished from the empirical hypothesis ('psychological egoism') that human beings seek to maximize their own good. Ethical egoism can approve of behaviour that benefits others, for often the best way to promote one's good is to form cooperative relationships. But the egoist cannot approve of an altruistic justification for such cooperation: altruism requires benefiting others merely for their sake, whereas the egoist insists that one's ultimate goal must be solely one's own good.

One way to defend ethical egoism is to affirm psychological egoism and then to propose that our obligations cannot outstrip our capacities; if we cannot help seeking to maximize our own well-being, we should not hold ourselves to a less selfish standard. But this defence is widely rejected, because psychological egoism seems too simple a conception of human behaviour. Moreover, egoism violates our sense of impartiality; there is no fact about oneself that justifies excluding others from one's ultimate end.

There is, however, a different form of egoism, which flourished in the ancient world, and is not vulnerable to this criticism. It holds that one's good consists largely or exclusively in acting virtuously, and that self-interest properly understood is therefore our best guide.

1 Definitions of 'egoism'

The term 'egoism' was introduced into modern moral philosophy as a label for a type of ethical theory that is structurally parallel to utilitarianism (see UTILITARIANISM). The latter theory holds that one ought to consider everyone and produce the greatest balance of good over evil; egoism, by contrast, says that each person ought to maximize their own good. Both theories are teleological, in that they hold that the right thing to do is always to produce a certain good (see TELEOLOGICAL ETHICS). But the utilitarian claims that the good that one is to maximize is the universal good – the good of all human beings and perhaps all sentient creatures. The egoist, on the other hand, holds that the good one is ultimately to aim at is only one's own (see GOOD, THEORIES OF THE).

This way of classifying ethical theories is due to Henry SIDGWICK, who regarded the choice between utilitarianism and egoism as one of the principal problems of moral philosophy. In *The Methods of Ethics* (1874), Sidgwick frames the issue in terms that assume that the good is identical to pleasure (a doctrine called 'hedonism') (see HEDONISM). He uses 'utilitarianism' for the view that one is to maximize the amount of pleasure in the universe, and holds that the only form of egoism worth considering is hedonistic egoism. Since few philosophers now accept the identity of pleasure and the good, the terms of the debate have changed. 'Egoism' is applied to any doctrine, whatever its conception of the good, that advocates maximizing one's own good.

Often this doctrine is called 'ethical egoism', to emphasize its normative status. By contrast, the term 'psychological egoism' is applied to an empirical hypothesis about human motivation. It holds that whenever one has a choice to make, one decides in favour of the action one thinks will maximize one's

own good. It is possible to agree that we are inevitably selfish in this way, but to regard this as an evil element in our nature. Conversely, it is possible to hold that although people ought to maximize their own good, they seldom try to do so. (In the remainder of this entry, 'egoism' will refer to ethical egoism, unless otherwise indicated.)

2 Egoism's treatment of altruism

A defender of egoism need not frown upon attachments to others, feelings of compassion, or beneficent acts. For it is open to the egoist to argue that these social ties are an effective means to one's own ends. For example, it is a matter of common sense that altruistic behaviour – behaviour intended to help others – is often advantageous, when it motivates others to respond in kind. What little one loses in simple acts of kindness may be more than compensated when others reciprocate.

Although egoists may argue that benefiting others is generally in one's interests, they give a controversial justification for such beneficence. It is widely agreed that one should at times benefit others for *their* sake (Aristotle, for example, in *Nicomachean Ethics*, considers this essential to the best kind of friendship). To act for the sake of others is to take their good as a sufficient reason for action. But this is exactly what egoists cannot accept. They hold that ultimately the only justification for acts of beneficence is that they maximize one's own good. Ultimately, one is not to benefit others for their sake, but for one's own. If 'altruism' is used (as it often is) to refer to behaviour that not only benefits others, but is undertaken for their sake, then egoism is opposed to altruism.

3 Arguments for and against

Philosophers have sometimes tried to refute egoism by showing that it contains a contradiction or is in some way self-undermining. The best known attempt is that of G.E. Moore in *Principia Ethica* (1903), but he has had few followers. Instead, Sidgwick's opinion that egoism is rational is generally accepted. But even if one agrees, one may ask whether there are good reasons for choosing egoism over other alternatives. Why must it always be a mistake to sacrifice one's good for the greater good of others? If a small loss in one's wellbeing can produce great gains for others, what is wrong with accepting that loss?

The egoist might at this point take refuge in psychological egoism. Although it is possible to affirm psychological egoism and reject ethical egoism – to agree that by nature we are ultimately self-seeking, and to condemn such behaviour as evil – few philosophers regard this as an appealing mix of theories. For what plausibility can there be in a standard of behaviour that we are incapable of achieving? The egoist may therefore respond to our question 'Why should we not sacrifice our good for the sake of others?' by urging us not to impose impossible standards upon ourselves. We do not in fact make such sacrifices, and should not blame ourselves for being the way we are.

The problem with this strategy is that psychological egoism has come under heavy attack in the modern period. Hobbes and Mandeville have been widely read as psychological egoists, and were criticized by such philosophers as Hutcheson, Rousseau and Hume, who sought to show that benevolence, pity and sympathy are as natural as self-love. Kant held against psychological egoism, that the rational recognition of moral principles can by itself motivate us and overcome self-love (see Kantian ethics). Perhaps the most influential critique of psychological egoism is that of Butler, who argued that by its nature self-love cannot be the only component of our motivational repertoire. He also pointed out that even if we feel gratification when we satisfy our desires, it cannot be inferred that such gratification is the object of those desires. The combined force of these attacks has left psychological egoism with few philosophical defenders.

At this point, an important challenge to ethical egoism should be noticed: although my circumstances, history or qualities may differ from yours in morally significant ways, and these differences may justify me in seeking my good in preference to yours, the mere fact that I am myself and not you is not by itself a morally relevant difference between us. That my good is mine does not explain why ultimately it alone should concern me. So, if my good provides me with a reason for action, why should not your good, or the good of anyone else, also provide me with a reason – so long as there are no relevant differences between us? The ideal of impartiality seems to support the conclusion that we should have at least some concern with others (see Impartiality). In fact, egoists implicitly accept a notion of impartiality, since they say that just as my ultimate end should be my good, yours should be your good. So they must explain why they accept this minimal conception of impartiality, but nothing stronger. There is nothing morally appealing about excluding all others from one's final end; why then should one do so?

4 An ancient form of egoism

The kind of egoism we have been discussing can be called 'formal', in that it makes no claim about what in particular is good or bad for human beings. It

holds instead that whatever the good is, it is one's own good that should be one's ultimate end. This is the conception one arrives at when one begins from Sidgwick's pairing of egoism with utilitarianism, then abstracts from his hedonism. A different kind of egoism, which might be called 'substantive', first proposes a concrete conception of the good, and then urges each of us to maximize our own good, so conceived. It is this form of egoism that flourished in the ancient world. Plato, Aristotle and the Stoics do not accept the formal principle that whatever the good is, we should seek only our own good, or prefer it to the good of others (see PLATO; ARISTOTLE; STOICISM). Instead, they argue for a specific conception of the good, and because the social virtues play so large a role in that conception, they regard self-love not as the enemy of virtue and the larger community but as an honourable motive, once it is developed in the proper direction (see EUDAIMONIA; VIRTUES AND VICES).

Even if psychological egoism is too simple a conception of human nature, it is undeniable that we normally have a deep concern for our own welfare. If self-love is a force that often conflicts with moral duty and inherently resists education, then human beings are necessarily deeply divided creatures. This is the Augustinian and Kantian picture. By contrast, the dominant strand of ancient ethics proposes a more optimistic conception of the human situation. It does not claim that one should seek one's own good, come what may for others; rather, by arguing that acting virtuously and acting well coincide, it seeks to undermine the common assumption that at bottom the self must come into conflict with others.

EINSTEIN, ALBERT (1879–1955)

Albert Einstein was a German-born Swiss and American naturalized physicist and the twentieth century's most prominent scientist. He produced the special and general theories of relativity, which overturned the classical understanding of space, time and gravitation. According to the special theory (1905), uniformly moving observers with different velocities measure the same speed for light. From this he deduced that the length of a system shrinks and its clocks slow at speeds approaching that of light. The general theory (completed 1915) proceeds from Hermann Minkowski's geometric formulation of special relativity as a four-dimensional spacetime. Einstein's theory allows, however, that the geometry of spacetime may vary from place to place. This variable geometry or curvature is associated with the presence of gravitational fields. Acting through geometrical curvature, these fields can slow clocks and bend light rays.

Einstein made many fundamental contributions to statistical mechanics and quantum theory, including the demonstration of the atomic character of matter and the proposal that light energy is organized in spatially discrete light quanta. In later life, he searched for a unified theory of gravitation and electromagnetism as an alternative to the quantum theory developed in the 1920s. He complained resolutely that this new quantum theory was not complete. Einstein's writings in philosophy of science developed a conventionalist position, stressing our freedom to construct theoretical concepts; his later writings emphasized his realist tendencies and the heuristic value of the search for mathematically simple laws.

ELIMINATIVISM

'Eliminativism' refers to the view that mental phenomena – for example, beliefs, desires, conscious states – do not exist. Although this can seem absurd on its face, in the twentieth century it has gained a wide variety of adherents, for example, scientific behaviourists, who thought that all human and animal activity could be explained in terms of the history of patterns of stimuli, responses and reinforcements; as well as some who have thought that neurophysiology alone is all that is needed.

Two immediate objections to eliminativism – for example, that it is incoherent because it claims there are no 'claims', and that it conflicts with data of which we are all immediately aware – arguably beg the question against the view. What is wanted is

non-tendentious evidence for the mind. Contrary to behaviourism, this seems to be available in the intelligent behaviour of most higher animals.

GEORGES REY

EMERSON, RALPH WALDO (1803–82)

The American philosopher and poet Ralph Waldo Emerson developed a philosophy of flux or transitions in which the active human self plays a central role. At the core of his thought was a hierarchy of value or existence, and an unlimited aspiration for personal and social progress. 'Man is the dwarf of himself', he wrote in his first book *Nature* (1836). Emerson presented a dire portrait of humankind's condition: 'Men in the world of today are bugs or spawn, and are called "the mass" and "the herd"'. We are governed by moods which 'do not believe in one another', by necessities real or only imagined, but also, Emerson held, by opportunities for 'untaught sallies of the spirit' – those few real moments of life which may nevertheless alter the whole.

Emerson's lectures drew large audiences throughout America and in England, and his works were widely read in his own time. He influenced the German philosophical tradition through Nietzsche – whose *The Gay Science* carries an epigraph from 'History' – and the Anglo-American tradition via William James and John Dewey. Emerson's major works are essays, each with its own structure, but his sentences and paragraphs often stand on their own as expressions of his thought.

EMOTION IN RESPONSE TO ART

The main philosophical questions concerning emotion in response to art are as follows. (1) What kind or type of emotions are had in response to works of art? (2) How can we intelligibly have emotions for fictional persons or situations, given that we do not believe in their existence? (This is known as 'the paradox of fiction'.) (3) Why do abstract works of art, especially musical ones, generate emotions in audiences, and what do audiences then have these emotions *towards*? (4) How can we make sense of the interest appreciators have in experiencing empathetically art that is expressive of *negative* emotions? (A particular form of this query is 'the paradox of tragedy'.) (5) Is there a special *aesthetic* emotion, raised only in the context of experience of art? (6) Is there an irresolvable tension between an emotional response to art and the demands of aesthetic appreciation? Answers to these questions depend to some extent on the conception of emotion adopted.

EMOTIONS AND MORALITY

See Morality and emotions

EMOTIONS, NATURE OF

What is an emotion? This basic question was posed by William James in 1884, and it is still the focus for a number of important arguments in the philosophy of mind and ethics. It is, on the face of it, a quest for a definition, but it is also a larger quest for a way of thinking about ourselves: how should we think about emotions – as intrusive or as essential to our rationality, as dangerous or as indispensable to our humanity, as excuses for irresponsibility or, perhaps, as themselves our responsibilities? Where do emotions fit into the various categories and 'faculties' of the mind, and which of the evident aspects of emotion – the various sensory, physiological, behavioural, cognitive and social phenomena that typically correspond with an emotion – should we take to be essential? Which are mere accompaniments or consequences?

Many philosophers hold onto the traditional view that an emotion, as a distinctively mental phenomenon, has an essential 'subjective' or 'introspective' aspect, although what this means (and how accessible or articulate an emotion must be) is itself a subject of considerable dispute. Many philosophers have become sceptical about such subjectivism, however, and like their associates in the social sciences have turned the analysis of emotions to more public, observable criteria – to the behaviour that 'expresses' emotion, the physiological disturbances that 'cause' emotion, the social circumstances and use of emotion language in the ascription of emotions. Nevertheless, the seemingly self-evident truth is that, whatever else it may be, an emotion is first of all a feeling. But what, then, is a 'feeling'? What differentiates emotions from other feelings, such as pains and headaches? And how does one differentiate, identify and distinguish the enormous number of different emotions?

ROBERT C. SOLOMON

EMOTIONS, PHILOSOPHY OF

Emotions have always played a role in philosophy, even if philosophers have usually denied them centre stage. Because philosophy has so often been described as first and foremost a discipline of reason, the emotions have often been neglected or attacked as primitive, dangerous or irrational. Socrates reprimanded his pupil Crito, advising that we should not give in to our emotions, and some of the ancient Stoic philosophers urged a life of reason free from the enslavement of the emotions, a life of *apatheia* (apathy). In Buddhism, too, much attention has been given to the emotions, which are treated as 'agitations' or *klesas*. Buddhist 'liberation', like the Stoic *apatheia*, becomes a philosophical ideal – freedom from the emotions.

Philosophers have not always downgraded the emotions, however. Aristotle defended the view that human beings are essentially rational animals, but he also stressed the importance of having the right emotions. David Hume, the eighteenth-century empiricist, insisted that 'reason is, and ought to be, the slave of the passions'. In the nineteenth century, although Hegel described the history of philosophy as the development of reason he also argued that 'nothing great is ever done without passion'. Much of the history of philosophy can be told in terms of the shifting relationship between the emotions (or 'passions') and reason, which are often at odds, at times seem to be at war, but ideally should be in harmony. Thus Plato painted a picture of the soul as a chariot with three horses, reason leading the appetites and 'the spirited part', working together. Nietzsche, at the end of the nineteenth century, suggested that 'every passion contains its own quantum of reason'.

Nietzsche's suggestion, that emotion and reason are not really opposites but complementary or commingled, has been at the heart of much of the debate about emotions since ancient times. Are emotions intelligent, or are they simply physical reactions? Are they mere 'feelings', or do they play a vital role in philosophy and in our lives?

ROBERT C. SOLOMON

EMOTIVE MEANING

Emotive meaning contrasts with descriptive meaning. Terms have descriptive meaning if they do the job of stating facts: they have emotive meaning if they do the job of expressing the speaker's emotions or attitudes, or exciting emotions or attitudes in others. Emotivism, the theory that *moral* terms have only or primarily emotive meaning, is an important position in twentieth-century ethics. The most important problem for the idea of emotive meaning is that emotive meaning may not really be a kind of meaning: the jobs of moral terms supposed to constitute emotive meaning may really be performed by speakers using moral terms, on only some of the occasions on which they use them.

There are two components in emotivist accounts of the function and meaning of moral terms. One is a matter of relations to the speaker: moral assertions serve to express the speaker's emotions or attitudes. The other is a matter of relations to the audience: moral assertions serve to commend things, or to arouse emotions or attitudes in the audience.

The most celebrated accounts of emotive meaning were developed by A.J. Ayer and C.L. Stevenson. Ayer argued on general metaphysical and epistemological grounds that moral terms can only express and excite emotions. Stevenson developed a more detailed theory, relying more on distinctively ethical considerations (see Emotivism). These theories are liable to make moral discussion seem irrational, and to make no distinction between moral argument and propaganda. R.M. Hare developed a theory designed to remedy these defects. He argued that sentences using paradigm moral terms like 'good', 'right' and 'ought' are really disguised imperatives. Since there is a logic of imperatives, there is room for rational moral argumentation, and moral argument can be distinguished from propaganda, even though moral assertions do not primarily state facts (see Prescriptivism).

The most important difficulties for the idea of emotive meaning can be raised by asking whether the emotive meaning of moral terms is a matter of the speech act performed by someone using these terms, and, if so, what kind of speech act? One can distinguish between locutionary, illocutionary and perlocutionary acts (or force). Locutionary acts are simply a matter of uttering certain words with certain senses and referents. Illocutionary acts lie *in* saying things; what illocutionary act one performs in uttering a sentence is determined together by the senses and referents of the words in the sentence and the context. Perlocutionary acts are done *by* saying things. That one performs a certain perlocutionary act is not guaranteed by performing an appropriate illocutionary act: it depends on further variable features of the context. Suppose Bob utters the words 'Down with the aristocrats!' before a large crowd in a revolutionary situation. Bob performs a locutionary act just by saying words with that meaning. In this context, Bob also performs the illocutionary act of *inciting* revolution. Bob's words may also, in that context, have the perlocutionary effect of *provoking* revolution; but this is not guaranteed by the locutionary or the illocutionary force of Bob's utterance. If Bob is sufficiently

unpopular, his advocating revolution may actually dampen revolutionary enthusiasm. This classification suggests that the order of explanation typically goes from the locutionary to the illocutionary and the perlocutionary: it is in virtue of the sense and reference of the words one utters and the context that one performs a certain illocutionary act, and that one performs certain perlocutionary acts. The presumption is that an account of meaning will begin with sense and reference; if it begins with illocutionary or perlocutionary acts, it may begin in the wrong place (see SPEECH ACTS).

Some early accounts of emotive meaning seem to identify the meaning of moral assertions with perlocutionary acts (for example, arousing emotions). But this seems both to be the wrong place to begin and to raise a further concern. If we think of meaning as a matter of convention, not (mere) causal variation, then causal correlations between utterances and the production of certain effects are not really meanings. Perhaps then emotive meaning is a matter of illocutionary force. Unfortunately, seeing emotive meaning as illocutionary force is also problematic; in addition to the general problem that an account of meaning apparently should not begin with the illocutionary, there is the specific problem that moral terms do not seem *always* to have the right kinds of illocutionary force. Consider the suggestion that 'good' is used to commend. While it may be true that the term 'good' as used in 'This is a good tennis racket', uttered in a sports shop has the illocutionary force of commending a tennis racket, 'good' as used in 'If you can't get a good one there, try the shop down the street' does not obviously seem to commend anything.

Moral arguments raise especially acutely a version of the same problem for the view that emotive meaning is illocutionary force. Consider the argument: 'Telling the truth is good; if telling the truth is good, getting your little brother to tell the truth is good; so getting your little brother to tell the truth is good.' This argument looks valid. But while 'telling the truth is good' in its occurrence as the first premise commends telling the truth, in its occurrence in the second premise it does not seem to commend anything. So, the suggestion is, emotivists cannot account for the validity of some moral arguments, because if meaning is understood as illocutionary force, it is not the same between different occurences of the same words in arguments. This problem is often called 'the problem of unasserted contexts' (in the second premise, 'telling the truth is good' occurs unasserted).

Fans of emotive meaning can respond to these criticisms. Hare, Blackburn and Gibbard have all offered solutions to the problem of unasserted contexts. It is certainly true that the meanings of *some* words (like 'promise') seem well explained by explaining the illocutionary act one performs in using them. Moreover, it is not an accident that, for instance, 'good' is often used to commend, while it is an accident if 'fast' is used to commend. Still, an attractive alternative to the theory that 'good' has emotive meaning is that 'good' *means* something like 'meets the relevant standards'. It is by virtue of this meaning that 'good' is often used to commend. Emotive force is then explained by meaning, not vice versa.

DAVID PHILLIPS

EMOTIVISM

Emotivists held that moral judgments express and arouse emotions, not beliefs. Saying that an act is right or wrong was thus supposed to be rather like saying 'Boo!' or 'Hooray!' Emotivism explained well the apparent necessary connection between moral judgment and motivation. If people judge it wrong to lie, and their judgment expresses their hostility, then it comes as no surprise that we can infer that they are disinclined to lie. Emotivism did a bad job of explaining the important role of rational argument in moral practice, however. Indeed, since it entailed that moral judgments elude assessment in terms of truth and falsehood, it suggested that rational argument about morals might be at best inappropriate, and at worst impossible.

In the early part of the twentieth century, under the influence of logical positivism, a new view about the nature of morality emerged: emotivism (see LOGICAL POSITIVISM). Emotivists held that when people say, 'It is wrong to tell lies', they express their hostility towards lying and try to get others to share that hostility with them. Moral claims were thus supposed to be very different from claims expressing beliefs. Beliefs purport to represent the world, and so are assessable in terms of truth and falsehood. Emotions, by contrast, do not purport to represent the world, so moral claims were supposed to elude such assessment (see MORAL JUDGMENT §1). Judging acts right and wrong was thus rather like saying 'Boo!' and 'Hooray!'

Emotivism had evident appeal. It is widely agreed that there is a necessary connection of sorts

between moral judgment and motivation. If someone judges telling lies to be wrong then they are motivated, to some extent, not to lie. But what people are motivated to do depends on what they approve of, or are hostile towards, not simply on what they believe (see MORAL MOTIVATION). Imagine, then, that someone's judgment that telling lies is wrong expressed a belief. In order to know whether they are inclined to lie or not we would then need to know, in addition, whether they approve of, or are hostile towards, telling lies. But we need to know no such thing. Knowing that they judge lying wrong suffices to know that they are disinclined to lie. This fits well with the idea that the judgment itself simply expresses hostility.

Emotivism also had its difficulties, however. Though emotivists admitted that rational argument about morals had an important role to play, their view entailed that this role was strictly limited. Since they agreed that less fundamental moral claims are entailed by more fundamental claims along with factual premises, and since they agreed that factual premises could be criticized rationally, they held that less fundamental moral claims must be rationally-based. Someone who judges lying wrong because they think that lies are harmful must, they thought, change their mind on pain of irrationality if shown that lying is harmless. But at the same time they insisted that fundamental moral claims – those that are not so derived, for example, the claim that it is wrong to cause harm – are immune from such rational criticism. This was the so-called 'fact/value gap' (see FACT/VALUE DISTINCTION).

It is unclear whether emotivists were consistent in allowing even this limited role for rational argument, however.

(1) If it is wrong to cause harm and lying causes harm then it is wrong to tell lies.
(2) It is wrong to cause harm.
(3) Lying causes harm.
Therefore, it is wrong to tell lies.

This argument is valid only if 'It is wrong to cause harm' in premises (1) and (2) means the same thing. If this phrase means different things then there is an equivocation and the argument is straightforwardly invalid. Emotivism entails that someone who asserts (2) expresses hostility towards causing harm. Yet whatever 'It is wrong to cause harm' means in (1), it most certainly does not serve to express such hostility. In (1) the phrase appears in the antecedent of a conditional. Someone who asserts (1) may thus even deny that it is wrong to cause harm. They need therefore have no hostility to express towards causing harm.

Philosophers sympathetic to emotivism have tried to rescue it from this objection. There is a real question whether emotivists themselves should ever have been interested in preserving an important role for rational argument about morals, however. If the function of moral judgment is simply to express emotions and arouse like emotions in others then it follows that rational argument is at best one way, and perhaps not a very good way, of achieving these aims. We might be more effective if we distracted people from the facts and used rhetoric, humiliation and brainwashing instead. It is hard to see how emotivists could find fault with the idea that a practice in which the use of such technologies was widespread could still constitute a perfectly proper *moral* practice.

The best emotivists could say at this point was, 'Boo for persuasion and brainwashing!' Philosophers who thought this response failed to acknowledge the central and defining role played by rational argument in moral practice concluded that emotivism extracted too high a price for its explanation of the necessary connection between moral judgment and motivation. Subsequent theorists have focused on whether an alternative explanation of the necessary connection is available, one which also accommodates the idea that rational argument plays such a central and defining role. No consensus on this issue has emerged, however.

If nothing else, emotivism succeeded in making clear how difficult it is to explain the necessary connection between moral judgment and motivation, together with the idea that rational argument plays a central and defining role in moral practice, if the emotions that cause our actions are assumed to be beyond rational criticism. Much recent work about the nature of morality proceeds by calling this assumption into question.

MICHAEL SMITH

EMPEDOCLES (*c*.495–*c*.435 BC)

Empedocles, born in the Sicilian city of Acragas (modern Agrigento), was a major Greek philosopher

of the Presocratic period. Numerous fragments survive from his two major works, poems in epic verse known later in antiquity as *On Nature* and *Purifications*.

On Nature sets out a vision of reality as a theatre of ceaseless change, whose invariable pattern consists in the repetition of the two processes of harmonization into unity followed by dissolution into plurality. The force unifying the four elements from which all else is created – earth, air, fire and water – is called Love, and Strife is the force dissolving them once again into plurality. The cycle is most apparent in the rhythms of plant and animal life, but Empedocles' main objective is to tell the history of the universe itself as an exemplification of the pattern.

The basic structure of the world is the outcome of disruption of a total blending of the elements into main masses which eventually develop into the earth, the sea, the air and the fiery heaven. Life, however, emerged not from separation but by mixture of elements, and Empedocles elaborates an account of the evolution of living forms of increasing complexity and capacity for survival, culminating in the creation of species as they are at present. There followed a detailed treatment of a whole range of biological phenomena, from reproduction to the comparative morphology of the parts of animals and the physiology of sense perception and thinking.

The idea of a cycle involving the fracture and restoration of harmony bears a clear relation to the Pythagorean belief in the cycle of reincarnations which the guilty soul must undergo before it can recover heavenly bliss. Empedocles avows his allegiance to this belief, and identifies the primal sin requiring the punishment of reincarnation as an act of bloodshed committed through 'trust in raving strife'. *Purifications* accordingly attacked the practice of animal sacrifice, and proclaimed prohibition against killing animals to be a law of nature.

Empedocles' four elements survived as the basis of physics for 2,000 years. Aristotle was fascinated by *On Nature*; his biology probably owes a good deal to its comparative morphology. Empedocles' cosmic cycle attracted the interest of the early Stoics. Lucretius found in him the model of a philosophical poet. Philosophical attacks on animal sacrifice made later in antiquity appealed to him as an authority.

MALCOLM SCHOFIELD

EMPIRICISM

In all its forms, empiricism stresses the fundamental role of experience. As a doctrine in epistemology it holds that all knowledge is ultimately based on experience. Likewise an empirical theory of meaning or of thought holds that the meaning of words or our concepts are derivative from experience. It is difficult to give an illuminating analysis of 'experience'. Let us say that it includes any mode of consciousness in which something seems to be presented to the subject, as contrasted with the mental activity of thinking about things. Experience, so understood, has a variety of modes – sensory, aesthetic, moral, religious and so on – but empiricists usually concentrate on sense experience, the modes of consciousness that result from the stimulation of the five senses.

It is obvious that not all knowledge stems directly from experience. Hence empiricism always assumes a stratified form, in which the lowest level issues directly from experience, and higher levels are based on lower levels. It has most commonly been thought by empiricists that beliefs at the lowest level simply 'read off' what is presented in experience. If a tree is visually presented to me as green I simply 'register' this appearance in forming the belief that the tree is green. Most of our beliefs – general beliefs for example – do not have this status but, according to empiricism, are supported by other beliefs in ways that eventually trace back to experience. Thus the belief that maple trees are bare in winter is supported by particular perceptual beliefs to the effect that this maple tree is bare and it is winter.

Empiricism comes in many versions. A major difference concerns the base on which each rests. A public version takes beliefs about what we perceive in the physical environment to be directly supported by experience. A phenomenalist version supposes that only beliefs about one's own sensory experience are directly supported, taking perceptual beliefs about the environment to get their support from the former sort of beliefs. The main difficulties for a global empiricism (all knowledge is based on experience) come from types of knowledge it is difficult to construe in this way, such as mathematical knowledge.

WILLIAM P. ALSTON

ENGELS, FRIEDRICH (1820–95)

Until the 1970s the most influential framework for understanding Marx's career and ideas was the one established by Engels. This framework was crucially

related to his understanding of philosophy and its supposed culmination in Hegel's systematic and all-encompassing idealism.

Engels claimed that Marx had grounded Hegel's insights in a materialism that was coincident with the physical and natural sciences of his day, and that Marx had identified a dialectical method applicable to nature, history and thought. With respect to history, Marx was said to have formed a 'materialist conception', from which his analysis of capitalist society and its 'secret' of surplus value were derived. Together these intellectual features were the core of the 'scientific socialism' which, Engels argued, should form the theory, and inform the practice, of the worldwide socialist or communist movement. This was to abolish the poverty and exploitation necessarily engendered, he claimed, by modern industrial production.

Philosophically the tenets of dialectical and historical materialism have been defended and modified by orthodox communists and non-party Marxists, and expounded and criticized by political and intellectual opponents. The three laws of dialectics, and the doctrine that history is determined by material factors in the last instance, have been attacked as tautologous and indeterminate. Engels's view that scientific socialism is a defensible representation of Marx's project has also been challenged by textual scholars and historians.

TERRELL CARVER

ENLIGHTENMENT, CONTINENTAL

The Enlightenment is frequently portrayed as a campaign on behalf of freedom and reason as against dogmatic faith and its sectarian and barbarous consequences in the history of Western civilization. Many commentators who subscribe to this view find the Enlightenment's cosmopolitan opposition to priestly theology to be dangerously intolerant itself, too committed to uniform ideals of individual self-reliance without regard to community or diversity, or to recasting human nature in the light of science. Modern debates about the nature of the Enlightenment have their roots in eighteenth-century controversies about the arts and sciences and about ideas of progress and reason and the political consequences of promoting them. Even when they shared common objectives, eighteenth-century philosophers were seldom in agreement on substantive issues in epistemology or politics. If they were united at all, it was by virtue only of their collective scepticism in rejecting the universalist pretensions of uncritical theology and in expressing humanitarian revulsion at crimes committed in the name of sacred truth.

ROBERT WOKLER

ENLIGHTENMENT, SCOTTISH

This term refers to the intellectual movement in Scotland in roughly the second half of the eighteenth century. As a movement it included many theorists – the best known of whom are David Hume, Adam Smith and Thomas Reid – who maintained both institutional and personal links with each other. It was not narrowly philosophical, although in the Common Sense School it did develop its own distinctive body of argument. Its most characteristic feature was the development of a wide-ranging social theory that included pioneering 'sociological' works by Adam Ferguson and John Millar, socio-cultural history by Henry Home (Lord Kames) and William Robertson as well as Hume's *Essays* (1777) and Smith's classic 'economics' text *The Wealth of Nations* (1776). All these works shared a commitment to 'scientific' causal explanation and sought, from the premise of the uniformity of human nature, to establish a history of social institutions in which the notion of a mode of subsistence played a key organizing role. Typically of the Enlightenment as a whole this explanatory endeavour was not divorced from explicit evaluation. Though not uncritical of their own commercial society, the Scots were in no doubt as to the superiority of their own age compared to what had gone before.

ENVIRONMENTAL ETHICS

Theories of ethics try to answer the question, 'How ought we to live?'. An environmental ethic refers to our natural surroundings in giving the answer. It may claim that all natural things and systems are of value in their own right and worthy of moral respect. A weaker position is the biocentric one,

arguing that living things merit moral consideration. An ethic which restricts the possession of moral value to human persons can still be environmental. Such a view may depict the existence of certain natural values as necessary for the flourishing of present and future generations of human beings. Moral respect for animals has been discussed since the time of the pre-Socratic philosophers, while the significance to our wellbeing of the natural environment has been pondered since the time of Kant and Rousseau. The relation of the natural to the built environment, and the importance of place, is a central feature of the philosophy of Heidegger. Under the impact of increasing species loss and land clearance, the work on environmental ethics since the 1970s has focused largely on one specific aspect of the environment – nature in the wild.

EPICUREANISM

Epicureanism is one of the three dominant philosophies of the Hellenistic age. The school was founded by Epicurus (341–271 BC). Only small samples and indirect testimonia of his writings now survive, supplemented by the poem of the Roman Epicurean Lucretius, along with a mass of further fragmentary texts and secondary evidence. Its main features are an anti-teleological physics, an empiricist epistemology and a hedonistic ethics.

Epicurean physics developed out of the fifth-century atomist system of Democritus. The only *per se* existents are bodies and space, each of them infinite in quantity. Space includes absolute void, which makes motion possible, while body is constituted out of physically indissoluble particles, 'atoms'. Atoms are themselves further measurable into sets of absolute 'minima', the ultimate units of magnitude. Atoms are in constant rapid motion, at equal speed (since in the pure void there is nothing to slow them down). Stability emerges as an overall property of compounds, which large groups of atoms form by settling into regular patterns of complex motion. Motion is governed by the three principles of weight, collisions and a minimal random movement, the 'swerve', which initiates new patterns of motion and obviates the danger of determinism. Atoms themselves have only the primary properties of shape, size and weight. All secondary properties, for example, colour, are generated out of atomic compounds; given their dependent status, they cannot be added to the list of *per se* existents, but it does not follow that they are not real. Our world, like the countless other worlds, is an accidentally generated compound, of finite duration. There is no divine mind behind it. The gods are to be viewed as ideal beings, models of the Epicurean good life, and therefore blissfully detached from our affairs.

The foundation of the Epicurean theory of knowledge ('Canonic') is that 'all sensations are true' – that is, representationally (not propositionally) true. In the paradigm case of sight, thin films of atoms ('images') constantly flood off bodies, and our eyes mechanically register those which reach them, neither embroidering nor interpreting. These primary visual data (like photographs, which 'cannot lie') have unassailable evidential value. But inferences from them to the nature of external objects themselves involves judgment, and it is there that error can occur. Sensations thus serve as one of the three 'criteria of truth', along with feelings, a criterion of values and psychological data, and *prolēpseis*, naturally acquired generic conceptions. On the basis of sense evidence, we are entitled to infer the nature of microscopic or remote phenomena. Celestial phenomena, for example, cannot be regarded as divinely engineered (which would conflict with the *prolēpsis* of god as tranquil), and experience supplies plenty of models adequate to explain them naturalistically. Such grounds amount to consistency with directly observed phenomena, and are called *ouk antimarturēsis*, 'lack of counter-evidence'. Paradoxically, when several alternative explanations of the same phenomenon pass this test, all must be accepted as true. Fortunately, when it comes to the foundational tenets of physics, it is held that only one theory passes the test.

In ethics, pleasure is the one good and our innately sought goal, to which all other values are subordinated. Pain is the only bad, and there is no intermediate state. Bodily pleasure becomes more secure if we adopt a simple lifestyle which satisfies only our natural and necessary desires, with the support of like-minded friends. Bodily pain, when inevitable, can be outweighed by mental pleasure, which exceeds it because it can range over past, present and future enjoyments. The highest pleasure, whether of soul or of body, is a satisfied state, 'static pleasure'. The short-term ('kinetic') pleasures of stimulation can vary this state, but cannot make it more pleasant. In striving to accumulate such pleasures, you run the risk of becoming dependent on them and thus needlessly vulnerable to fortune. The primary aim should instead be the minimization of pain. This is achieved for the body through a simple lifestyle, and for the soul through the study of physics, which offers the most prized 'static' pleasure, 'freedom from disturbance' (*ataraxia*), by

eliminating the two main sources of human anguish, the fears of god and of death. It teaches us that cosmic phenomena do not convey divine threats, and that death is mere disintegration of the soul, with hell an illusion. Being dead will be no worse than not having yet been born. Physics also teaches us how to evade determinism, which would turn moral agents into mindless fatalists: the indeterministic 'swerve' doctrine (see above), along with the logical doctrine that future-tensed propositions may be neither true nor false, leaves the will free.

Although Epicurean groups sought to opt out of public life, they respected civic justice, which they analysed not as an absolute value but as one perpetually subject to revision in the light of changing circumstances, a contract between humans to refrain from harmful activity in their own mutual interest.

EPIPHENOMENALISM

Epiphenomenalism is a theory concerning the relation between the mental and physical realms, regarded as radically different in nature. The theory holds that only physical states have causal power, and that mental states are completely dependent on them. The mental realm, for epiphenomenalists, is nothing more than a series of conscious states which signify the occurrence of states of the nervous system, but which play no causal role. For example, my feeling sleepy does not cause my yawning – rather, both the feeling and the yawning are effects of an underlying neural state.

Mental states are real, and in being conscious we are more than merely physical organisms. Nevertheless, all our experiences, thoughts and actions are determined by our physical natures. Mental states are actually as smoke from a machine seems to be, mere side effects making no difference to the course of Nature.

EPISTEMOLOGY

Introduction

Epistemology is one of the core areas of philosophy. It is concerned with the nature, sources and limits of knowledge (see Knowledge, concept of). There is a vast array of views about those topics, but one virtually universal presupposition is that knowledge is true belief, but not mere true belief. For example, lucky guesses or true beliefs resulting from wishful thinking are not knowledge. Thus, a central question in epistemology is: what must be added to true beliefs to convert them into knowledge?

1 The normative answers: foundationalism and coherentism

The historically dominant tradition in epistemology answers that question by claiming that it is the quality of the reasons for our beliefs that converts true beliefs into knowledge (see Epistemology, history of). When the reasons are sufficiently cogent, we have knowledge. This is the normative tradition in epistemology. An analogy with ethics is useful: just as an action is justified when ethical principles sanction its performance, a belief is justified when epistemic principles sanction accepting it (see Justification, epistemic; Epistemology and ethics). The second tradition in epistemology, the naturalistic tradition, does not focus on the quality of the reasons for beliefs but, rather, requires that the conditions in which beliefs are acquired typically produce true beliefs (see Internalism and externalism in epistemology; Naturalized epistemology).

Within the normative tradition, two views about the proper structure of reasons have been developed: foundationalism and coherentism. By far, the most commonly held view is foundationalism. It holds that reasons rest on a foundational structure comprising 'basic' beliefs (see Foundationalism). The foundational propositions, though justified, derive none of their justification from other propositions. (Coherentism, discussed below, denies that there are foundational propositions).

These basic beliefs can be of several types. Empiricists (such as Hume and Locke) hold that basic beliefs exhibit knowledge initially gained through the senses or introspection (see A posteriori;

EMPIRICISM). Rationalists (such as DESCARTES, LEIBNIZ and SPINOZA) hold that at least some basic beliefs are the result of rational intuition (see A PRIORI; RATIONALISM). Since not all knowledge seems to be based on sense experience, introspection or rational intuition, some epistemologists claim that some knowledge is innate (see KNOWLEDGE, TACIT; KANT, I.; PLATO). Still others argue that some propositions are basic in virtue of conversational contextual features. That is, some propositions are taken for granted by the appropriate epistemic community (see CONTEXTUALISM, EPISTEMOLOGICAL).

Foundationalists hold that epistemic principles of inference are available which allow an epistemic agent to reason from the basic propositions to the non-basic (inferred) propositions. They suggest, for example, that if a set of basic propositions is explained by some hypothesis and additional confirming evidence for the hypothesis is discovered, then the hypothesis is justified. A notorious problem with this suggestion is that it is always possible to form more than one hypothesis that appears equally well confirmed by the total available data, and consequently no one hypothesis seems favoured over all its rivals (see INDUCTION, EPISTEMIC ISSUES IN). Some epistemologists have argued that this problem can be overcome by appealing to features of the rival hypotheses beyond their explanatory power. For example, the relative simplicity of one hypothesis might be thought to provide a basis for preferring it to its rivals (see SIMPLICITY (IN SCIENTIFIC THEORIES); THEORETICAL (EPISTEMIC) VIRTUES).

In contrast to foundationalism, coherentism claims that every belief derives some of its justification from other beliefs (see KNOWLEDGE AND JUSTIFICATION, COHERENCE THEORY OF; BOSANQUET, B.; BRADLEY, F.H.). All coherentists hold that, like the poles of a tepee, beliefs are mutually reinforcing. Some coherentists, however, assign a special justificatory role to those propositions that are more difficult to dislodge because they provide more support for the other propositions and are more supported by them. The set of these special propositions overlaps the set of basic propositions specified by foundationalism.

There are some objections aimed specifically at foundationalism and others aimed specifically at coherentism. But there is one deep difficulty with both traditional normative accounts. This problem, known as the 'Gettier problem' (after a famous three-page article by Edmund Gettier in 1963), can be stated succinctly as follows (see GETTIER PROBLEM): suppose that a false belief can be justified (see FALLIBILISM), and suppose that its justificatory status can be transferred to another proposition through deduction or other principles of inference (see DEDUCTIVE CLOSURE PRINCIPLE). Suppose further that the inferred proposition is true. If these suppositions can be true simultaneously – and that seems to be the case – the inferred proposition would be true, justified (by either foundationalist or coherentist criteria) and believed, but it clearly is not knowledge, since it was inferred from a false proposition. It is a felicitous coincidence that the truth was obtained.

One strategy for addressing the Gettier Problem remains firmly within the normative tradition. It employs the original normative intuition that it is the quality of the reasons that distinguishes knowledge from mere true belief. This is the defeasibility theory of knowledge. There are various defeasibility accounts but, generally, all of them hold that the felicitous coincidence can be avoided if the reasons which justify the belief are such that they cannot be defeated by further truths.

2 The naturalistic answers: causes of belief

There is a second general strategy for addressing the Gettier Problem that falls outside of the normative tradition and lies squarely within the naturalistic tradition (see QUINE, W.V.). As the name suggests, the naturalistic tradition describes knowledge as a natural phenomenon occurring in a wide range of subjects. Adult humans may employ reasoning to arrive at some of their knowledge, but the naturalists are quick to point out that children and adult humans arrive at knowledge in ways that do not appear to involve any reasoning whatsoever. Roughly, when a true belief has the appropriate causal history, then the belief counts as knowledge (see KNOWLEDGE, CAUSAL THEORY OF).

Suppose that I am informed by a reliable person that the temperature outside the building is warmer now than it was two hours ago. That certainly looks like a bit of knowledge gained and there could be good reasons provided for the belief. The normativists would appeal to those good reasons to account for the acquisition of knowledge. The naturalists, however, would argue that true belief resulting from testimony from a reliable source is sufficient for knowledge (see SOCIAL EPISTEMOLOGY; TESTIMONY).

Testimony is just one reliable way of gaining knowledge. There are other ways such as sense perception, memory and reasoning. Of course, sometimes these sources are faulty (see MEMORY, EPISTEMOLOGY OF). A central task of naturalized epistemology is to characterize conditions in which reliable information is obtained. Thus, in some of its forms, naturalized epistemology can be seen as a branch of cognitive psychology, and the issues can be addressed by empirical investigation.

Now let us return to the Gettier Problem. Recall that it arose in response to the recognition that truth might be obtained through a felicitous coincidence. The naturalistic tradition ties together the belief and truth conditions of knowledge in a straightforward way by requiring that the means by which the true belief is produced or maintained should be reliable.

3 Scepticism

The contrast between normative and naturalized epistemology is apparent in the way in which each addresses one of the most crucial issues in epistemology, namely, scepticism (see SCEPTICISM). Scepticism comes in many forms. In one form, the requirements for knowledge become so stringent that knowledge becomes impossible, or virtually impossible, to obtain. For example, suppose that a belief is knowledge only if it is certain, and a belief is certain only if it is beyond all logically possible doubt. Knowledge would then become a very rare commodity (see DOUBT).

Other forms of scepticism only require good, but not logically unassailable, reasoning. We have alluded to scepticism about induction. That form of scepticism illustrates the general pattern of the sceptical problem: there appear to be intuitively clear cases of the type of knowledge questioned by the sceptic, but intuitively plausible general epistemic principles appealed to by the sceptic seem to preclude that very type of knowledge.

Another example will help to clarify the general pattern of the sceptical problem. Consider the possibility that my brain is not lodged in my skull but is located in a vat and hooked up to a very powerful computer that stimulates it to have exactly the experiences, memories and thoughts that I am now having. Call it the 'sceptical hypothesis'. That hypothetical situation is clearly incompatible with the way I think the world is. Now, it seems to be an acceptable normative epistemic principle that if I am justified in believing that the world is the way I believe it to be (with other people, tables, governments and so on), I should have some good reasons for denying the sceptical hypothesis. But, so the argument goes, I could not have such reasons; for if the sceptical hypothesis were true, everything would appear to be just as it now does. So, there appears to be a conflict between the intuition that we have such knowledge and the intuitively appealing epistemic principle. Thus, scepticism can be seen as one instance of an interesting array of epistemic paradoxes (see PARADOXES, EPISTEMIC).

Of course, epistemologists have developed various answers to scepticism. Within the normative tradition, there are several responses available. One of them is simply to deny any epistemic principle – even if it seems initially plausible – that precludes us from having what we ordinarily think is within our ken (see COMMONSENSISM; CHISHOLM, R.M.; MOORE, G.E.; REID, T.). Another response is to examine the epistemic principles carefully in an attempt to show that, properly interpreted, they do not lead to scepticism. Of course, there is always the option of simply declaring that we do not have knowledge. Whatever choice is made, some initially plausible intuitions will be sacrificed.

Within the naturalistic tradition, there appears to be an easy way to handle the sceptical worries. Possessing knowledge is not determined by whether we have good enough reasons for our beliefs but, rather, whether the processes that produced the beliefs in question are sufficiently reliable. So, if I am a brain in a vat, I do not have knowledge; and if I am not a brain in a vat (and the world is generally the way I think it is), then I do have knowledge. Nevertheless, those within the normative tradition will argue that we are obliged to withhold full assent to propositions for which we have less than adequate reasons, regardless of the causal history of the belief.

4 Recent developments in epistemology

Some recent developments in epistemology question and/or expand on some aspects of the tradition. Virtue epistemology focuses on the characteristics of the knower rather than individual beliefs or collections of beliefs (see VIRTUE EPISTEMOLOGY). Roughly, the claim is that when a true belief is the result of the exercise of intellectual virtue, it is, *ceteris paribus*, knowledge. Thus, the virtue epistemologist can incorporate certain features of both the normative and naturalist traditions. Virtues, as opposed to vices, are good, highly prized dispositional states. The intellectual virtues, in particular, are just those deep dispositions that produce mostly true beliefs. Such an approach reintroduces some neglected areas of epistemology, for example, the connection of knowledge to wisdom and understanding.

In addition, there are emerging challenges to certain presuppositions of traditional epistemology. For example, some argue that there is no set of rules for belief acquisition that are appropriate for all peoples and all situations. Others have suggested that many of the proposed conditions of good reasoning, for example 'objectivity' or 'neutrality', are not invoked in the service of gaining truths, as traditional epistemology would hold, but rather they are employed to prolong entrenched power and (at least in some cases) distort the objects of knowledge (see FEMINIST EPISTEMOLOGY).

In spite of these fundamental challenges and the suggestions inherent in some forms of naturalized epistemology that the only interesting questions are

empirically answerable, it is clear that epistemology remains a vigorous area of inquiry at the heart of philosophy.

EPISTEMOLOGY AND ETHICS

Epistemology and ethics are both concerned with evaluations: ethics with evaluations of conduct, epistemology with evaluations of beliefs and other cognitive acts. Of considerable interest to philosophers are the ways in which the two kinds of evaluations relate to one another. Philosophers' explorations of these relations divide into two general categories: examination of potential analogies between the two fields, and attempts to identify necessary or conceptual connections between the two domains.

There is little doubt that there are at least superficial similarities between ethics and epistemology: one might say that ethics is about the appraisal of social behaviour and agents, while epistemology is about the appraisal of cognitive acts and agents. On the other hand, the widely held view that behaviour subject to moral evaluation is free and voluntary while beliefs are not, suggests one important disanalogy between the two fields.

RICHARD FELDMAN

EPISTEMOLOGY, HISTORY OF

Introduction

Epistemology has always been concerned with issues such as the nature, extent, sources and legitimacy of knowledge. Over the course of Western philosophy, philosophers have concentrated sometimes on one or two of these issues to the exclusion of the others; rarely has a philosopher addressed all of them. Some central questions are:

(1) What is knowledge – what is the correct analysis or definition of the concept of knowledge?
(2) What is the extent of our knowledge – about what sorts of things is knowledge actually held?
(3) What are the sources of knowledge – how is knowledge acquired?
(4) Is there any genuine knowledge?

Concern with the first question has predominated in philosophy since the mid-twentieth century, but it was also discussed at some length in antiquity. Attention to the second question seems to have begun with Plato, and it has continued with few interruptions to the present day. The third question was also important in antiquity, but has also been a central focus of epistemological discussion through the medieval and early modern periods. The fourth question raises the issue of scepticism, a topic which has generated interest and discussion from antiquity to the present day, though there were some periods in which sceptical worries were largely ignored.

Various attempts to answer these questions throughout the history of philosophy have invariably served to raise additional questions which are more narrow in focus. The principal one which will be treated below can be stated as:

(5) What is a justified belief – under which conditions is a belief justified?

There has been but occasional interest in this last question in the history of philosophy; however, it has been a crucial question for many philosophers in the twentieth century.

1 Ancient philosophy

The extant writings of the Presocratics primarily address issues in metaphysics and cosmology; epistemological concerns appear to arise first in Plato. In the *Meno* Plato tells the story of a slave boy who has had no formal education and in particular

has never studied geometry. In a conversation with Socrates, the boy is led to answer questions about a geometrical figure and his answers turn out to be correct. The boy is led to assert that when given a square with side S, so that its area is S^2, then a square of exactly $2S^2$ is formed by taking as its side the diagonal of the original square. The boy could hardly have learned this earlier, since he is uneducated. Plato takes this example to show that the boy knew the geometrical truth all along and, more generally, that the boy's soul existed earlier in a state of knowledge. Indeed, he held that the boy's soul earlier knew all truths but had since forgotten them. What the boy was really doing in his conversation with Socrates was recollecting something he had forgotten. And this Plato takes to hold for everyone: what we think of as coming to know is really recollecting.

The soul or knower may have come into existence and so it would not have always had knowledge; or it may have always been in existence but at some time acquired its stock of knowledge; or it may have always been and always had knowledge. Plato certainly rejects the first option, especially in the *Phaedo* where he argues for the indestructibility and indefinite prior existence of the soul. He also appears to reject the second option (*Meno* 86b) so that his view would be that the soul always exists and earlier had a great deal of knowledge without having acquired this knowledge at some time.

The *Meno* also contains a distinction between true belief and knowledge (97d–98b). Knowledge, Plato says, is 'tied down' or tethered in a way that true opinion is not. This view, which seems to suggest that knowledge is justified true belief, is taken up again in the *Theaetetus*, where Plato suggests that knowledge is true belief plus an account or *logos* (201d). However, several attempts to explicate the notion of an account are rejected, and the dialogue ends inconclusively. It is not clear whether Plato rejects this account of knowledge outright, or whether he is best construed as rejecting this definition given the defective notions of an account (*Theaetetus* 210a–b).

In the *Republic*, especially in Book V, Plato addresses a version of our question pertaining to the extent of knowledge. There he distinguishes between knowledge at one extreme and ignorance at the other, and he roughly identifies an intermediate state of opinion or belief. Each of these states of mind, Plato says, has an object. The object of knowledge is what is or exists; the object of ignorance is what does not exist; and the object of belief is some intermediate entity, often taken as what is becoming or the sensible physical world of objects and their qualities (*Republic* 508d–e; *Cratylus* 440a–d). What truly exists for Plato are unchanging Forms, and it is these which he indicates as the true objects of knowledge (see FORMS, PLATONIC). Moreover, knowledge is infallible, while belief is fallible (*Republic* 477e). In thus identifying knowledge with infallibility or certainty, Plato is departing widely from the view of knowledge given in *Meno* and *Theaetetus*. And, his account of the extent of our knowledge is also severely restricted: genuine knowledge is had only of the higher realm of immutable, ideal Forms (see FALLIBILISM; PLATO §§11, 15).

Aristotle discusses a special form of knowledge, scientific knowledge, in the *Posterior Analytics*. A science, as Aristotle understands it, is to be thought of as a group of theorems each of which is proved in a demonstrative syllogism. In the first instance, a demonstrative syllogism in science S is a syllogistic argument whose premises are first principles of S. These first principles, in turn, must be true, primary, immediate, better known than and prior to the conclusion, which is further related to them as effect to cause (*Posterior Analytics* 71b 21–22). First principles are primary and immediate when they are not themselves demonstrable. Still, such principles are known; indeed, they are better known than the demonstrated conclusion, a contention which may mean either that they are more familiar than the conclusion, or perhaps more certain than the conclusion. The first principles are also said to be prior to the conclusions in an epistemic way: knowledge of the conclusion requires knowledge of the first principles, but not conversely. And the first principles must explain why it is that the demonstrated conclusion is true.

The science can be extended by taking theorems proved from first principles as premises in additional demonstrative syllogisms for further conclusions. Here, too, the premises must explain the truth of the conclusion. A science will be the sum of all such theorems, demonstrated either from first principles or from already demonstrated theorems in appropriate syllogisms. And a person who carries through all these syllogisms with relevant understanding has knowledge of all of the theorems.

The first principles, however, are also known though they are not demonstrated as theorems. On this point Aristotle gives what may be the first statement of a regress argument in favour of a kind of foundationalist position (see FOUNDATIONALISM). Some might hold that even the first principles must be demonstrated if they are to be known. This would lead to an infinite regress, as these first principles would themselves be conclusions of syllogisms whose premises were other first principles which, to be known, would have to be demonstrated. To avoid the infinite regress, one would need either to allow for circular demonstration, or

to agree that the first principles are not themselves known but are mere suppositions. Aristotle rejects all these options in favour of the foundationalist view in which the first principles are known even though they are not demonstrated. For him, one has an immediate, intuitive grasp of the first principles. However, his foundationalism is to be distinguished from those discussed below, because his foundations are made up of fundamental principles of special sciences.

In *De Anima*, Aristotle discusses perception and perceptual knowledge. Among perceptible objects, he distinguishes between proper and common sensibles. Common sensibles are those objects that are perceivable by more than one sense, for example, the shape of a box which can be both seen and touched. Proper sensibles are those objects that are only perceivable by one sense, for example, colour can only be seen. With respect to these proper objects, Aristotle says that one cannot be in error, or one cannot be deceived (*De Anima* 418a 9–13; 428b 17–21). So, if a person sees a white cat, they can be deceived about whether it is a cat, but not in thinking that there is white present. The same would apply to proper objects of other senses. If we then assume, as Aristotle seems to have done, that the impossibility of being deceived about *X* is sufficient for having knowledge about *X*, then we reach the conclusion that we have certain perceptual knowledge about the proper objects of each sense. What is not clear is whether Aristotle felt that one could not be mistaken about actual qualities of physical objects, such as their colours; or rather about an object's perceived qualities. Clearly the former is much less plausible than the latter (see ARISTOTLE §6).

2 Hellenistic philosophy

The Hellenistic phase of philosophy occupies several centuries after Aristotle's death (322 BC), and is notable for its three schools of philosophy: Epicureanism, Stoicism, and Scepticism (see SCEPTICISM). The sceptical tradition, however, continued well into the second century AD.

The Epicurean school supported an even more thoroughgoing empiricism than we find in Aristotle, and is best known for its doctrine that all perceptions are true. In perception, Epicurus says, thin layers of atoms are emitted from external physical objects (*eídōla*) and reach our senses, which passively receive and register these *eídōla* exactly as they are. But this, *per se*, is not to have knowledge of the external causes of our experiences of *eídōla*. For that, we need to make well-grounded inferences to the existence and nature of the external objects. Epicurus, however, maintains that these inferences, doubtless causal ones, can be legitimately made, and thus that there is genuine perceptual knowledge of physical objects. The fact that these inferences may fare poorly under sceptical scrutiny is not a matter to which Epicurus paid special attention, probably because he did not think that the defeat of sceptical concerns was a necessary project within epistemology (see EPICUREANISM).

The Stoic position is much less optimistic. Their central concept is that of a cognitive impression. In normal conditions a red object appears red, and one has the thought (cognitive impression) 'This is red'. Such a cognitive impression, Stoics held, cannot fail to be true. It is not, by itself, knowledge of the red object however, because the person might not assent to this impression. One has knowledge only if one assents to a cognitive impression and this assent is firm, the sort of assent that one cannot be persuaded to withhold. Ordinary people fall short of assent of this firm sort, and so really have mere opinions about objects. Only the wise man typically engages in firm assent to only cognitive impressions; so only the wise man truly has knowledge of such objects (see STOICISM).

In thus restricting knowledge, the Stoic position is actually close to a sceptical doctrine. The two schools of ancient scepticism, the Academic and the Pyrrhonian, had notable differences and each had points of development over nearly five centuries, ending with Sextus Empiricus in the late second century AD. A common feature of each school, though, is an attack on claims to knowledge. For any argument towards a conclusion which goes beyond sensory appearances, sceptics maintained that an equally strong counter-argument could be given. Other sceptical arguments point to the relativity of all perception, depending on changes in the percipient or in the observation conditions or perspectives, and conclude that we do not gain knowledge of external physical objects via perception. Also, if a criterion for knowledge-acquisition is relied upon – such as perception or causal inductive inference as in Epicurus – then this criterion could be questioned as itself being far from evidently reliable. These sceptical arguments were properly taken to lead to the suspension of belief (*epochē*), rather than to the assertion that there is no knowledge. Moreover, the Pyrrhonian sceptics noted that the ultimate goal of their arguments was a non-epistemic one, that of *ataraxía* or being undisturbed. This calm state is presumed achievable once beliefs have been suspended and one is content to carry on one's life dealing only with appearances (see PYRRHONISM; SEXTUS EMPIRICUS).

Scepticism was challenged in the early medieval period by Augustine in his *Contra Academicos*, in which he dealt critically with the arguments of

Cicero, the last of the great academic sceptics (see AUGUSTINE; CICERO, M.T.). However, scepticism was not a major concern in the Middle Ages, and did not receive special philosophical attention again until the Renaissance.

3 Medieval philosophy

Medieval philosophy is concerned primarily with issues in metaphysics, logic and natural theology, less with epistemological topics. Aquinas and Ockham, however, were two thinkers for whom epistemological questions were of great interest and importance.

Aquinas closely followed Aristotle on many points, including Aristotle's account of scientific knowledge (see §1 above). Thus, *scientia* or genuine scientific knowledge is restricted to propositions proved in demonstrative syllogisms whose premises are themselves known. And, as in Aristotle, Aquinas holds that this account of *scientia* requires as premises in some demonstrative syllogisms, first principles that are known *per se*, immediately and without inference. That there must be such first principles is shown by the fact that otherwise one is faced with either an infinite regress of items of knowledge or with circularity. The former is ruled out because nobody can achieve an infinite number of inferential steps; and circularity, wherein one knows *p* on the basis of *q* and knows *q* on the basis of *p*, is dismissed because it allows that a single proposition, *p*, can both be and not be epistemically prior to *q*. For both Aquinas and Aristotle, the premises of a demonstrative syllogism are epistemically prior to their conclusions in the sense that one cannot know the conclusion without first knowing the premises, though not vice versa.

First principles of demonstrative syllogisms, for Aquinas, are necessary truths, propositions in which there is a necessary connection between the predicate and subject concepts. To grasp or know a first principle, then, requires that one grasp this necessary connection. To achieve this, one must first possess the general concepts expressed by the subject and predicate terms. Accordingly, Aquinas gives an account of how we may acquire such concepts. To do this, one must abstract the intelligible species or forms of objects from the sense impressions received in perception of them. Ultimately, then, knowledge of the first principles depends on perception, though it is not epistemically based on perception.

William of Ockham makes an interesting break with Aquinas' conception of knowledge. Part of the break concerns the fact that Ockham allows for knowledge of contingent truths, as opposed to restricting knowledge to necessary truths. Another difference concerns perception. Aquinas held that, in perception, one has an experience of an image or phantasm from which by some cognitive mechanism (called an agent intellect) one abstracts an intelligible species or form of the perceived object. By means of this abstracted item one knows some universal aspect of the perceived object (see AQUINAS, T. §11). Ockham disagrees with a number of these points. For him, in perception of an external physical object, there is no intermediary such as a phantasm or sensible species. Instead, the object is itself perceived directly, an experience which Ockham regards as an intuitive cognition. In this respect, Ockham's account is close to that of perceptual direct realism. But he also holds epistemic direct realism, because he argues that the direct visual awareness of the external object suffices for one to acquire immediate and certain knowledge of the existence of the object and of some of its qualities. In this regard, one is 'knowing the singular' rather than something universal; and the proposition one comes to know in perception is a contingent truth. So, in perceiving a red box, one might come to know that there is a red box before one.

Sceptical worries could intrude, even here. One might see a red box and still be mistaken in one's resulting belief. One might think, therefore, that forming the belief as a result of a red-box visual experience does not suffice for knowledge. Ockham is aware of this objection, but he has a two-part answer to it. First, he notes that the mere possibility of mistaken belief does not rule out knowledge. He also notes that aligning the concept of certainty with the impossibility of mistaken belief is itself an error. Certainty, he says, requires only the absence of actual doubt or grounds for doubt. Certainty of this weaker sort, he holds, is all that is needed for knowledge (see WILLIAM OF OCKHAM).

This is a decisive break with earlier views, both with respect to the concept of certainty and with respect to its relation to the concept of knowledge. But, with one or two notable exceptions, these ideas were not taken up by many writers until much later.

4 Modern philosophy: Descartes

It is customary to begin the story of modern philosophy with Descartes, but we need to start a little farther back with a discussion of scepticism. We have noted that ancient scepticism was hardly known during the Middle Ages. In the sixteenth century, however, the old sceptical texts of Cicero were re-published and works by Sextus Empiricus were translated into Latin and thus made available to scholars. These texts and their arguments became

very important to those on both sides of disputes over the legitimacy and extent of religious knowledge, an issue given great currency by the Reformation and the Counter-Reformation. Under the direct influence of Sextus Empiricus, MONTAIGNE published his *Apology for Raimond Sebond* (1576) in which he set forth sceptical arguments and recommended suspension of belief on practically all topics. His disciple, Pierre Charron, popularized sceptical doctrines even further. This sceptical climate was well known to Descartes in the first half of the seventeenth century. Still later, Pierre Bayle's *Dictionary*, which contained a number of sceptical entries, was to have a great deal of influence on Berkeley and Hume (see BAYLE, P.).

Descartes was thoroughly aware of the sceptical writings and debates of his time, and of the development of sceptical literature since Montaigne. But Descartes himself was no sceptic; on the contrary, he set out to defeat scepticism on its own terms, that is, by finding some knowledge which is completely certain and thus immune to sceptical criticism.

To accomplish this, Descartes used the method of doubt, a method wherein a proposition is considered false provided there is even the slightest possible ground for doubting it. Whole classes of propositions would then be excluded as not known: everything which one believes on the basis of the senses is dubitable by this criterion, and so is not knowledge. The many propositions of science also qualify as dubitable, and so are not items of knowledge. Indeed, it is possible, Descartes reasons, that an evil demon systematically deceives us all, even with respect to the necessary truths of mathematics. If such a demon is even possible, then there is at least the possibility of grounds for doubt, and so virtually nothing would qualify as knowledge.

Descartes contends, however, that such an evil demon cannot deceive him in one case, namely when he thinks in any way. Even when the thinking in which he engages is a case of doubting, whenever Descartes thinks he must exist, and thus he affirms as certain '*Cogito, ergo sum*' – I think, therefore I exist. This is an item about which he cannot be deceived, and it is thus for Descartes indubitable or certain, and assuredly a case of knowledge.

Descartes' epistemological project then becomes one of seeing whether any other genuine certain knowledge can be derived from this very slender base. He finds first a criterion for certainty: those thoughts or ideas which are clear and distinct are also true. In fact, he says that clarity and distinctness of a thought or idea suffices to assure him of its truth. Using this criterion together with his certain knowledge that he exists, Descartes constructs a complex causal argument for the existence of God. The clarity and distinctness of the thoughts that God is not a deceiver and that God would not allow wholesale deception is then put to work to try to derive propositions formerly excluded as dubitable by the method. Especially important here are propositions concerning the existence of external physical objects.

Descartes' project is thus a foundationalist one of an austere sort. For him, the foundations are restricted to the propositions that he himself exists, that he has certain ideas, and that God exists. From these, utilizing the criterion of clarity and distinctness, the foundations can be augmented to include propositions about immediately experienced sensations. However, derivations of other propositions from these foundational ones have to be restricted to deductions that themselves can be seen to be clear and distinct. If the derivations were inductive, then grounds for doubting the conclusions would be possible. And even if the derivations were deductive, if one did not see that they were validly made from individually indubitable premises, once again the possibility of grounds for doubting the conclusions would arise. Only if the possibility of such grounds are eliminated can these derived conclusions count as items of knowledge.

Descartes, thus, perpetuates and even emphasizes the close conceptual connection between knowledge and the strictest sort of certainty. He also gives currency to the problem of the external world, that is, the problem of deriving propositions concerning external physical objects from foundational propositions made up mostly of propositions concerning sensations. Of course, Descartes has propositions about a non-deceiving God in his foundations, unlike later writers who grappled with this problem. So armed, Descartes claims in the sixth Meditation that he can derive the general claims that there are external physical objects and that they have at most the so-called primary qualities. But even if these claims count as items of knowledge, so that to some extent scepticism is vanquished, it does not seem that Descartes secures knowledge of individual propositions about physical objects and their qualities. For he concedes that, with respect to these, error is possible in the best of circumstances, even with God's help (see DESCARTES, R. §§3–5).

5 Modern philosophy: Spinoza and Leibniz

It is customary to classify Spinoza and Leibniz along with Descartes as rationalists. In epistemology, rationalism is the view which stresses the role of reason in the acquisition of knowledge, and correspondingly downplays the role of experience

or observation. A limiting case of rationalism, then, would be a position which held that only reason is operative in knowledge acquisition. It is perhaps Spinoza who comes closest to a rationalist position of this sort (see RATIONALISM).

For Spinoza, a true idea is one which must agree with its object (*Ethics*: I, dx. 6). An adequate idea is one which, considered by itself, has an internal sign or intrinsic mark of a true idea (*Ethics*: II, def. 4). Having an adequate idea, then, suffices to recognize it as true. There is no need of a clarity-and-distinctness criterion for determining which ideas are true. In this respect, Spinoza differs sharply from Descartes.

Spinoza distinguishes three levels of knowledge. The first is that which we receive in sense perception or from what he calls 'signs', as when the sight of some printed words causes one to remember something. First-level knowledge is not strictly knowledge, however, but rather opinion or imagination. Second-level knowledge or reason (*ratio*) is knowledge of the properties of objects and of relations between properties. Third-level knowledge is intuitive science, which Spinoza says 'advances from an adequate idea of the formal essence of certain attributes of God to the adequate knowledge of the essence of things' (*Ethics*: II prop. XL, schol. 2). Third-level knowledge proceeds from one thing to another in the sense that a person who has an adequate idea of the formal essence of one of God's attributes may logically infer to adequate knowledge of the essence of things.

Knowledge is adequate when one may logically infer, merely from having an adequate idea of *x*, to some general truth about *x* (second level), or to some truth about *x*'s effects (third level). Thus, on the second level, from an adequate idea of body one may infer that all bodies are capable of motion, and thus knowledge of this proposition is adequate. And from the adequate idea of the essence of a divine attribute, one may infer to the essence or nature of objects, and thus the proposition concerning the essence of the objects is adequately known.

Spinoza certainly thinks we have adequate ideas, and so have adequate knowledge (*Ethics*: II, prop. XXXIV). And he holds that the propositions known at the second and third levels are necessarily true (*Ethics* XLI). So, it looks very much as if Spinoza is committed to the view that second- and third-level knowledge is a priori, that is, knowledge that need not rely on experience, and to this degree he would qualify as a rationalist (see SPINOZA, B. DE §§7–8).

Leibniz, the other great philosopher usually classified as a rationalist, did not develop a systematic view in epistemology. His classification as a rationalist is no doubt tied to two important strands of his thought. For simple subject-predicate propositions, fundamental for Leibniz, he proposed the predicate-in-notion principle. This is the thesis that the concept of the predicate in such a proposition is contained in the concept of the subject. It seems as though this principle implies that all subject-predicate propositions are necessarily true. For the conceptual-containment doctrine amounts to the claim that such propositions are true in virtue of their meanings or are conceptually true, and this would make them necessarily true. This has the twofold result that all truth is necessary truth, given that subject-predicate propositions are fundamental; and, that all knowledge is or can be a priori, the latter on the assumption that if a proposition is a necessary truth, then it is a priori knowable. If Leibniz held these views, his status as a rationalist is secure.

Leibniz strove to ward off these consequences, however, by an account of analysis. He held that in a necessary proposition, the concept-containment feature allows for the proposition to be analysed or reduced to an identity proposition in a finite number of steps. Contingent truths, however, cannot be so analysed, despite the concept-containment thesis. Instead, in an infinite number of steps of analysis, such propositions would converge on an identity proposition. (Sometimes Leibniz suggests that such propositions can be analysed into identity propositions by God.) So, not all truths are necessary, and thus neither is all knowledge a priori.

There is a strong rationalist side to Leibniz, however, which emerges in the second strand of his thought, namely, his defence of innate truths. In a dispute with Locke, Leibniz contended that there are numerous innate concepts and principles in pure mathematics, logic, metaphysics and ethics. These innate truths are all necessary truths, and they are all knowable a priori. The senses, Leibniz says, merely function as the occasions by and on which these truths are brought to attention (see LEIBNIZ, G.W. §§8–9).

6 Modern philosophy: Locke and Berkeley

Locke provides a strong empiricist contrast to both Spinoza and Leibniz. For Locke, the fundamental items of all cognitions are ideas, which divide into those of sensation and those of reflection. The former are acquired in perception, the latter in introspective attention to the contents and workings of one's own mind. Perception and reflection, for Locke, make up experience, and the fundamental empiricist thesis is that all ideas and all knowledge derive from experience. It follows from empiricism so construed that no ideas are innate. For Locke, the

mind is a 'blank tablet' at birth, and it is only by experience that it acquires its stock of ideas.

In *An Essay concerning Human Understanding* Locke defines knowledge as the perception of the agreement or disagreement of two ideas (1689: IV, I, 1 and 5). This definition has the immediate effect of restricting all knowledge to ideas, something Locke recognizes and appears to accept (1689: IV, II, 1). It also seems to have the effect of restricting knowledge to relations between ideas. The definition and the restriction accord well with most of what Locke says about knowledge.

Intuitive knowledge is the perception of the agreement or disagreement between two ideas 'immediately by themselves, without the intervention of any other' (*Essay* (1689): IV, II, 1). Perception that white is not the same as black, for example, is immediate and requires no intermediate idea between those of white and black. Intuitive knowledge, for Locke, is the most certain: it is both irresistible and infallible.

Locke seems to desert his definition of knowledge in three important cases, however, and in two of these cases intuitive knowledge is at issue. One has, for instance, intuitive knowledge of individual ideas, as when one knows that some pain is very sharp (*Essay*: IV, II, 1). Locke also maintains that one has intuitive knowledge of oneself. In such a case, even if an idea of reflection is had, self-knowledge is not a perception of an agreement or disagreement of two ideas. Moreover, it is knowledge about the self, which is not an idea or group of ideas. In this case, Locke departs not merely from his definition, but also from his explicit claim about the extent of our knowledge.

Demonstrative knowledge, for Locke, requires that each step in the demonstration be intuitively known, and that the relation between the premises and the conclusion also be intuitively known. Meeting these constraints on demonstrative knowledge assures that it is virtually as certain as intuitive knowledge. But meeting these constraints is not easy, especially in long demonstrations where one must keep in mind inferences made earlier. In such cases, Locke indicates, one's degree of certainty with respect to the conclusion will drop and one will not have demonstrative knowledge properly speaking.

Locke's account of sensitive knowledge marks a third point at which he seems to depart from his official definition of knowledge and the restriction of knowledge to our ideas. Sensitive knowledge is knowledge of the existence of external physical objects. It is not as certain as intuitive or demonstrative knowledge, yet it is still knowledge. And Locke clearly thinks that we have such knowledge, at least in those cases when an external physical object is actually present to one's senses (*Essay*: IV, III, 5). Locke conceives of sensitive knowledge of presently perceived physical objects as inferential knowledge. From knowledge of presently experienced ideas one infers that there is an external physical object present as the cause of those ideas. Locke is untroubled by sceptical worries over whether such inferences can be legitimately made.

The distinction between intuitive and certain knowledge of ideas, and sensitive knowledge of physical objects, with the latter knowledge inductively based on the former, is indicative of Locke's foundationalist position. It differs from that proposed by Descartes, however, in two important ways. First, the propositions making up the foundations are different. For Locke, these are confined to propositions about individually experienced ideas, or to propositions describing a perceived agreement or disagreement between ideas. Thus, Locke's commitment to empiricism dictates what the foundations shall be. Another difference comes in the inferences from the foundational propositions which Locke finds acceptable. He allows for both deductive and inductive inferences, whereas for Descartes permissible inferences may only be deductive. Locke thus marks a liberalization of the foundationalist strictures imposed by Descartes (see LOCKE, J. §§2–3).

Berkeley was critical of Locke's account of knowledge of physical objects, as was Hume (though, unlike Berkeley, Hume did not mention Locke by name). Locke notes that inductive inferences from currently experienced ideas to physical objects will succeed only when there is a conformity between the ideas and the physical object (*Essay*: IV, IV, 3). Ideas, that is, have to represent the physical objects in some way. Berkeley denies that ideas can serve this role. An idea, he says, can only be like or similar to another idea, not a physical object. Moreover, even allowing for this similarity, the needed inductive inferences depend on and so require that one establish that some ideas do adequately represent objects. To accomplish this, Berkeley argues, one must be in a position to compare the ideas and the physical object. However, as Berkeley notes, this is a position one cannot occupy given Locke's account of perception, which restricts immediate perception to ideas, and so never allows for immediate perception of physical objects. Locke's overall theory, according to Berkeley, really leads to scepticism about physical objects.

To avoid this, Locke could drop the demand that currently experienced ideas conform to or represent objects. Berkeley suggests that this manoeuvre is no help because Locke's theory still requires inductive inferences from the ideas to the physical objects. He notes that the inferences at issue would be explanatory – the supposition that there are physical

objects present causally explains the ideas one experiences – but denies their cogency (*Principles of Human Knowledge* 1710). A simpler and thus better explanation of our ideas, Berkeley argues, would be the supposition that they are caused by a single powerful being such as God.

Locke's empiricist version of foundationalism is often attributed to Berkeley. However, Berkeley seems to reject such a theory in favour of a foundationalism both more expansive and more modest. It is more expansive because Berkeley allows that we have immediate and certain knowledge of physical object propositions as well as propositions about currently experienced ideas. Hence, while Berkeley accepts an empiricist version of foundationalism, the propositions he is willing to count as foundational include many more than are countenanced on Locke's theory. Berkeley's theory is more modest in regard to the concept of certainty. For him, a proposition is certain provided that one has no actual grounds for doubting it. It is not further required that mistaken belief is logically impossible. In this way, Berkeley is able to contend that physical object propositions are certain, and he can avail himself of a much more modest criterion of what is to count as a foundational proposition. On this point, Berkeley lines up with Ockham (see §3 above), and with certain twentieth-century philosophers (see §8 below).

Berkeley also aimed to refute scepticism regarding the external world. He argues that this may be achieved provided one can find a way to allow for the immediate perception of physical objects. His thought is that if we perceive physical objects immediately, then we also have immediate and certain knowledge of them. He claims that these results are all achieved by abandoning realism regarding physical objects, and embracing instead a thesis which entails that objects exist if and only if they are perceived. Thus, he defends the phenomenalist thesis that a physical object is identical to a collection of ideas (see PHENOMENALISM). Objects which are collections are immediately perceivable so long as one immediately perceives some of their constituent members. So, the phenomenalist thesis regarding objects allows Berkeley to defend the view that physical objects are immediately perceivable, and hence to argue for the claimed refutation of scepticism and a more expansive foundationalism. In these respects, Berkeley claims, he is merely defending the views of common sense (see BERKELEY, G. §§5–9).

7 Modern philosophy: from Hume to Peirce

Both Locke and Berkeley accept the theory that in every perceptual experience, one is immediately aware of at least one idea. Hume follows them in this, but he distinguishes between impressions, which are our more lively and original perceptions, and ideas, which are less lively. In seeing a red cup, one experiences a red impression (or perhaps an impression of red), while in remembering the cup one attends to an idea of the red cup. Hume's fundamental principle is that all ideas are derived from impressions, and in this regard he is a thorough-going empiricist about concepts (ideas).

He also seems to accept epistemic empiricism, at least in the sense that a proposition about an object not currently present to one's senses would count as knowledge only if that proposition were derivable from propositions about currently experienced impressions. Hume denies that physical-object propositions can be deduced from propositions about impressions. He also notes that inductive inference is not something that can be given a non-circular justification. Hence, the inductive inferences from impression propositions to physical-object propositions are not justified, and so scepticism regarding physical objects results.

Hume does note, however, that nature or our psychological make-up does not allow us actually to accept scepticism, or to refrain from making inductive inferences, especially causal ones. He may mean that the fact that we are built in such a way, psychologically, that we make inductive inferences beyond our impressions to beliefs about physical objects itself constitutes being justified in having these beliefs and making these inferences. If so, then Hume is an early externalist about justification and knowledge (see INTERNALISM AND EXTERNALISM IN EPISTEMOLOGY). Or, he may mean that we can only describe the beliefs we have and the inferences we make; questions about the justification of these inferences and whether the beliefs count as knowledge cannot be settled. In that case, Hume accepts the sceptical results noted above (see HUME, D. §2).

Two very important critics of what they regarded as Humean scepticism were REID and KANT. Reid argued that Hume's scepticism was generated by acceptance of the theory of ideas (impressions), arguing that no philosopher had ever given any good reason for accepting this theory, and that it gives a mistaken account of perception in any case. The correct account, for Reid, is a complex version of direct realism in which we gain immediate and certain knowledge of physical objects. The beliefs we gain in direct perception of objects are typically irresistible, and it is a first principle for Reid, a matter of common sense, that perception is reliable and so such beliefs are justified and constitute knowledge.

Hume's scepticism did not extend to what he called 'relations of ideas'. These included the necessary truths of mathematics, and of these Hume allowed we can have a priori knowledge

(*Enquiry Concerning Human Understanding* 1748: IV, 1). It was only with respect to some statements of matters of fact that Hume was sceptical. For Kant, relations of ideas are analytic statements, while matters of fact are synthetic (see A PRIORI; A POSTERIORI; ANALYTICITY). He felt that there was a third category, however, which Hume had missed, namely synthetic a priori propositions. These are necessary truths in which the meanings of the predicate terms are not contained in the meanings of their subject terms; hence, they are synthetic. But Kant argued that the necessary truths of geometry and arithmetic are synthetic a priori, as are some very general principles of science, and these can all be known a priori. He argues that the a priori concepts he calls categories genuinely apply to objects we experience, and that our experience actually is objective in the sense that it is of real physical objects. Kant also held that having experience of objects suffices for having knowledge of such objects, and so scepticism regarding physical objects is incorrect (see KANT, I. §§4, 6).

Hegel's *Phenomenology of Spirit* (1807) contains an extended criticism of a doctrine often thought to be common to all empiricists, namely that there is immediate knowledge of something *given* in perception (for the classical empiricists, ideas), and that this knowing is passive in the sense that it is unmediated by concepts. This criticism, of course, would apply to any variant of empiricism, including a view which holds that physical objects and not subjective ideas are perceptually given and are objects of passive, immediate knowledge. Hegel's view is that there simply is no knowledge of this sort. Rather, all knowledge is conceptually mediated. Hegel seems to have drawn the conclusion that there is nothing at all which is given, a doctrine later given great currency in the twentieth century (see HEGEL, G.W.F. §5).

Charles PEIRCE was another important critic of foundationalism, both empiricist and Cartesian. Against the former, Charles Peirce held that no empirical belief is certain – we can be mistaken in any empirical belief – and neither is it unrevisable – we can be reasonably motivated to give up any empirical belief in the light of new evidence. These two points make up part of Peirce's fallibilism (see FALLIBILISM). The Cartesian programme is criticized on the grounds that wholesale doubt is not a psychologically possible action, so that Descartes' method of securing foundations for knowledge does not succeed.

8 Twentieth century

The empiricist tradition continued into the twentieth century in sense-datum theories of the sort found in Russell, with special attention paid to knowledge of the external physical world. It was argued that, in any perceptual experience, one is immediately aware of sense-data rather than physical objects. Sense-data are taken to be phenomenal objects having qualities such as colour and shape (see SENSE-DATA). Immediate awareness of sense-data is acquaintance, itself a form of certain knowing, namely, knowing objects rather than propositions about objects. Propositional knowledge of objects is knowledge by description, and it is inferential, based upon acquaintance knowledge of sense-data.

The needed inferences were to be underwritten by analytical phenomenalism, that is, the thesis that all physical-object sentences are analysable into, and so equivalent in meaning to, sets of sense-datum sentences. Given this equivalence, it was felt, inferences from sense-datum sentences to physical-object sentences would be secured as legitimate; thus the problem of the external world was solved.

Related theories were defended by AYER and C.I. LEWIS. Ayer dropped the notion of acquaintance. Sense-data were taken as items of immediate awareness, which typically issued in incorrigible propositional knowledge. Lewis dispensed with sense-data; he expressed the foundational sentences using ordinary idioms such as 'This seems red', but he made the same demands on these as Ayer did of sense-datum sentences. They are certain, and the basis of all other empirical knowledge. As in Russell, inferences from these were supposed sanctioned by analytical phenomenalism.

Interestingly enough, G.E. MOORE also defended a sense-datum theory of perception, but did not couple it with an empiricist version of foundationalism. Rather, he defended common sense, which for him included the view that there are many particular material-object propositions which are known immediately and with certainty. For instance, Moore claimed to know, immediately and with certainty, that a certain mantelpiece was closer to his body than a specific bookcase. For Moore, knowledge of this proposition and of many other material-object propositions need not be based on more secure knowledge of sense-data. In this regard, then, Moore's view is more a version of epistemic direct realism than it is empiricist foundationalism.

The programme of empiricist foundationalism and analytical phenomenalism was widely criticized. The alleged incorrigibility or certain knowledge of sense-data was influentially attacked by J.L. AUSTIN. All empirical sentences, he argued, are corrigible because in forming a belief about an object, such as is expressed by 'This is red', one is classifying the object as among the red things and so is relying on

one's wholly fallible memory of other comparably red items. Moreover, certainty or incorrigibility is not needed for knowledge. Many critics argued that certainty in the sense of lack of actual grounds for doubt was a more adequate analysis of this concept, and in this sense many physical-object sentences would count as certain. Analytical phenomenalism was also criticized, principally by Chisholm (see PHENOMENALISM). He showed that physical-object sentences do not entail sense-datum sentences, and hence are not equivalent to them.

Ayer and Lewis also were in rough agreement on the definition of the concept of knowledge. They held that propositional knowledge is justified true belief, an account shared by many others. Edmund Gettier argued that this definition was incorrect. His idea was that one could have a true justified belief which is not knowledge in a situation in which one reasons from some already justified beliefs to a new belief that, as it happens, is coincidentally true. Since it would then be a matter of coincidence that one's belief was correct, it would not count as knowledge, even though it was a justified belief because it was knowingly inferred from already justified beliefs (see GETTIER PROBLEM).

Gettier's 1963 article generated a great deal of interest. While some argued that his argument was unsatisfactory, a majority assumed that he was more or less right, and many new analyses of knowledge were proposed, including many which incorporated the justified true belief analysis as a part. What has emerged as perhaps the most promising and least prone to new counter-examples is the defeasibility analysis. The key idea is that of defeated justification: where one is justified in believing a proposition *p* on the basis of evidence *e*, one's justification is defeated when there is a true proposition *q*, such that the conjunction (*e*&*q*) does not justify *p*. The defeasibility analysis would then be that knowledge is justified, true, undefeated belief. Sophisticated versions of the defeasibility analysis have been worked out in detail by a number of authors, including Klein, Lehrer and Swain (see KNOWLEDGE, DEFEASIBILITY THEORY OF).

Closely connected to the concept of knowledge is the concept of a justified belief, and a number of important theories of epistemic justification have been developed, the principal ones being foundational theories, coherence theories and reliability theories (see JUSTIFICATION, EPISTEMIC). We have already noted Cartesian and empiricist versions of foundationalism. In recent years some philosophers have defended modest versions of foundationalism. That is, they have defended the view that a belief would be justified if and only if either it were a basic, foundational belief, or were inferrable from basic beliefs. The modesty of the theory would then derive from the fact that basic beliefs need not be certain or incorrigible; it would suffice if the basic beliefs were to be non-inferentially justified. Beliefs are non-inferentially justified when their justification need not result from being based on or inferrable from other justified beliefs.

Many philosophers have found even modest foundationalism suspect, primarily because they have found problematic the notion of a basic, non-inferentially justified belief. Some have accordingly avoided this notion altogether, and developed coherence theories of justified belief. The core idea in all such coherence theories is that a belief is justified if and only if it is a member of a system of beliefs, and this system of beliefs is coherent. A number of different accounts of coherence have been proposed, but most favoured has been that of explanatory coherence. On such a view, some beliefs (explainees) in the coherent system are justified because they are explained by other beliefs in the system; the remaining beliefs in the system are justified in virtue of their role in explaining the explainees. A problem for these theories has been to provide a reasonable way of selecting those beliefs within the system which are to be explained (see KNOWLEDGE AND JUSTIFICATION, COHERENCE THEORY OF).

The most widely discussed reliabilist theory has been the reliable-process theory. The core idea here is that a belief is justified if and only if it is caused by, or causally sustained by, a reliable process. A process is reliable when it has a high truth-ratio; that is, when that process produces more true beliefs than false ones. Typical processes selected as reliable belief-forming or belief-sustaining ones are perception, memory, introspection, and inferring or reasoning.

A problem which has proved especially vexing for supporters of the reliable-process theory is that of generality. Any specific belief is produced (sustained) by a process token which is an instance of many different process types. The generality problem is essentially that of fixing how broadly to individuate the process types in question.

9 Recent issues

In a reliable-process theory cognizers may have no knowledge or awareness of the processes which cause or causally sustain their beliefs, or of the reliability of these processes. Most foundational and coherence theories, however, construe the notion of justification in such a way that a person's belief is justified only if they have some access to, or awareness of, whatever it is that serves to justify that belief. Theories with this access condition are generally thought of as internalist theories; those

which dispense with the access requirement are externalist. Though widely discussed, no fully adequate resolution of the question of whether an access requirement should be imposed on a theory of justification has yet gained general acceptance (see INTERNALISM AND EXTERNALISM IN EPISTEMOLOGY).

Proponents of reliable-process theories have typically tried to develop a naturalistic theory (see NATURALIZED EPISTEMOLOGY). Minimally, a naturalistic epistemological theory is one in which key epistemic concepts such as knowledge and justification are analysed or explained in a form which makes use only of non-epistemic concepts. A more radical form of naturalism in epistemology, proposed by Quine, dispenses outright with the normative elements of traditional epistemology, and reconceives the subject as a part of empirical psychology (see QUINE, W.V. §2). On this view, epistemology becomes a wholly descriptive discipline, one which studies how beliefs are formed, and how they are related to what we take evidence to be. Whether a minimal or more radical form of naturalized epistemology is acceptable is an open question at present.

Issues in social epistemology have also loomed large recently, as have topics in feminist epistemology. Within the former, two important questions are whether social factors play a role in determining whether a person has knowledge or justified belief, and whether non-individuals such as groups or institutions can be said to have knowledge or justified beliefs (see SOCIAL EPISTEMOLOGY). Within feminist epistemology a leading question has been whether women acquire knowledge in ways that differ from methods of knowledge acquisition open to men. Another important issue has been whether social and cultural factors as they affect women have a bearing on what it is that women know (see FEMINIST EPISTEMOLOGY).

All these recent developments in epistemology are being vigorously pursued and explored. They have served to expand and enrich the field in ways not appreciated just a few decades ago.

EPISTEMOLOGY, INDIAN SCHOOLS OF

Each classical Indian philosophical school classifies and defines itself with reference to a foundational text or figure, through elaboration of inherited positions, and by disputing the views of other schools. Moreover, the schools have literatures that define them in a most concrete sense, literatures that in some cases stretch across twenty centuries and comprise hundreds of texts. And without exception, every school takes a stance on the nature of knowledge and justification, if only, as with the Mādhyamika Buddhist, to attack the positions of others. A blend of epistemology, ontology or metaphysics, and, sometimes, religious or ethical teachings constitutes the view of most schools, and sometimes only very subtle shifts concerning a single issue differentiate one school's stance from another's.

Relabelling schools of Indian epistemology using terminology forged in Western traditions ('foundationalism', 'coherentism', and so on) risks skewing the priorities of classical disputants and distorting classical debates. Nevertheless, there are positions shared across some of the schools, as well as refinements of position that apparently because of merit received greater attention in classical discussions and appear to deserve it still. Given the broad context of world philosophy, selectivity cannot be free from bias stemming from a sense of reverberation with non-Indian traditions of thought. With these warnings in mind, we may proceed to examine three important approaches within classical Indian philosophy to questions of epistemology.

First, the late Yogācāra Buddhist philosophers, Dignāga (b. *c.*480), Dharmakīrti (*c.*600–60) and followers, present a complex first-person approach to questions about knowledge that is constrained by an anti-metaphysical theme (found in earlier Buddhist treatises), along with a phenomenalism that grows out of a vivid sense of the real possibility of *nirvāṇa* experience as the supreme good. Their thought also exhibits an academic strand that is sensitive to non-Buddhist philosophical discussions. Second, a reliabilism identifying sources of veridical awareness is the most distinctive, and most central, approach to epistemology within classical Indian philosophy as a whole. Even the Yogācāra first-person approach gets framed in terms of reliable sources (perception and inference as *pramāṇas*, 'sources of knowledge'). Philosophers of diverse allegiance make contributions to what may be called this *field* of thought (as opposed to an *approach*), since, to repeat, it is the philosophical mainstream. However, the Nyāya school (the 'Logic' school) leads in most periods. Finally, the Brahmanical school known as Mīmāṃsā ('Exegesis'), supplemented in

particular by centuries of reflection under an Advaita Vedānta flag, develops what can be called an ethics of belief, namely, that we should accept what we see (for example) as real (and the propositional content of perceptual awarenesses as true), what we are told by another as true, what we infer as true, and so on, except under specific circumstances that prove a proposition false or at least draw it into question. The (Nyāya) epistemological mainstream is moved to incorporate a variation on this position; for Mīmāṃsā and Advaita, 'self-certification' (*svataḥprāmāṇya*), or the intrinsic veridicality of cognition, defines an alternative approach to questions about knowledge, awareness and a presumed obligation to believe.

EQUALITY

Introduction

Equality has long been a source of political and philosophical controversy. A central question about equality is how one might link empirical or moral claims about the extent to which persons are equal to judgements about the moral acceptability or unacceptability of social inequalities, and in particular how far considerations of equality license social action to bring about greater social equality. A traditional liberal argument holds that approximate equality of human strength makes it prudent for humans to place themselves under a common political authority, thus producing a justification for equality before the law. But any generalization of this argument ignores the cases where strength is unequal and the resulting balance of power unjust. Equality of worth is a principle recognized in many philosophical traditions, but its broad acceptance leaves open many problems of interpretation. In particular, it is not clear how far the principle calls for greater equality of social conditions. Persons may derive a sense of worth from enjoying the fruits of their labour, and this will legitimately block some redistribution; certain inequalities may work to everyone's advantage; and the impartial concern of the equality principle may be at odds with the sense of ourselves as persons with specific attachments. In this context, some have wanted to soften the interpretation of equality to mean equality of opportunity or merely that inequalities should not be cumulative, although how far these moves are justified is a matter for dispute. By contrast, challenges to the equality principle from considerations of incentives, desert or difference can more easily be met.

1 The idea of equality

Nearly 2,500 years ago Aristotle remarked in *The Politics* (336–22 BC) that disputes over equality and inequality were generally behind the warfare within states. Nowadays in topics as diverse as the distribution of income and wealth, access to public services, the distribution of work and employment opportunities, the political representation of different social groups and the control of natural resources among nations, the issue of equality plays a central, but controversial, role.

The idea of equality occurs in political philosophy in three main ways. First, it has sometimes been used as a purported description of certain features of human life in society, most notably in the claim that human beings are approximately equal in strength. Second, it is used as a principle of action to the effect that persons should be treated as having equal moral worth. Third, it is used to indicate a supposedly desirable set of social conditions, for example 'one person, one vote' or a more equal distribution of income. A central issue is how far one can employ premises drawn from the first two senses of the term to evaluate social, economic and political inequalities in the third sense. In particular the question arises as to how far social inequalities are just, or at least justifiable (see Justice §5).

To speak of equality without qualification is to speak elliptically. Strictly speaking, equality is a relation that holds between objects or persons in respect of some common characteristic that they share. In most respects, human beings are unequal: they exhibit differences of height, weight, intelligence, manual dexterity, earning capacity and so on. Moreover, if society or governments were to seek to equalize some goods or resources, for example income, they would render unequal some other aspect of social relations, for example hourly rates of pay when people work for different lengths of time.

The upshot of these logical points is that the idea of equality needs to be embedded within a broader

theory of politics and society in order to be given a specific content. No political theory aims at equality pure and simple. It aims instead at specific types of equality thought to be morally or socially important.

2 Equality of strength

Given the diversity of human beings, can it ever be said that all human beings are equal in any respect? In *Leviathan* (1651), Hobbes suggested that, although differing in bodily and mental capacities, human beings were equal in that it would be always possible for one person to kill another, an idea picked up by Hume in the eighteenth century and H.L.A. Hart in the twentieth.

According to this tradition, such rough equality of strength makes it prudent or rational for human beings to place themselves under a common body of rules comprising a system of mutual forbearance and agreement. Thus, despite persistent differences in wealth and status in society, equality of obligation under the law flows from equality of strength in some hypothesized pre-legal situation. Political agents should therefore recognize a common system of authority not merely as wise but also as just.

This line of thought can be carried too far, however. For the equality of strength condition only holds under rather specific circumstances, and where it does not hold the weak are vulnerable. One intuitive idea of justice is that bargaining advantage should not be allowed to prevail where this would threaten certain fundamental interests of persons; political power will thus only be legitimate when it protects the vulnerable (see Justice §4).

3 Equality of moral worth

If we cannot establish a normatively adequate theory of politics solely on the notion of an approximate equality of strength, the idea of equality will have to be given an irreducible moral content. This introduces the second sense of the idea: namely, equality means that all persons are to be thought of as having the same moral worth and are entitled to equal respect and consideration in the treatment of their interests. Although associated with contemporary liberal political thought, both in its utilitarian and its Kantian variants (see Liberalism), this idea has also found a place in many other philosophical and religious traditions, including Jewish and Christian political thought, the Stoic tradition, and the Confucianism associated with Mencius. Currents of thought within Islam, as well as breakaway sects from Hinduism, have also advanced the idea that there is an equal moral worth of all persons. However, can any specific implications about the ordering of social relations be derived from a principle that thinkers of such varying political and philosophical persuasions have endorsed?

One issue here concerns the terms in which we spell out the implications of greater equality. Greater social equality in principle leaves open the question of what exactly is to be equalized: should it be resources, welfare or some other aspect of human life? There are sound arguments for taking any one of these possibilities as the basis of public policy.

However the issue of measurement is resolved, the central justificatory arguments for equality claim that the principle of equal moral worth places limits on what actions a state may pursue (for example, it may not privilege the interests of some at the expense of others), and that a sense of personal worth depends upon the political, social and economic institutions in which members of society participate. Yet, it is easy to see that, although in general this claim may be true, there is no simple way in which the precise nature of these connections can be ascertained.

Suppose it is allowed that people's sense of self-worth depends upon the social institutions in which they participate, so that poverty and social deprivation will undermine a person's sense of self-worth. The extent to which this assumption will license a general equalization of social and economic resources is not obvious. Thus, some libertarians have claimed that such equalization will require practices of redistribution that in effect treat the wealthy as mere means to the attainment of some social goal, in a way that is inconsistent with the respect for persons that the principle of equal worth requires (see Libertarianism).

In this simple form the libertarian argument does not carry much conviction, since it does not show why requiring persons to fulfil putative obligations under a principle of justice is to treat them merely as means. However, it does at least indicate that there may be constraints on the way in which the practice of redistribution is accomplished and that persons should, by and large, enjoy the fruits of their own labour.

Quite apart from these libertarian objections to the equalization of property, it has also been argued that the principle of equality it should be recognized that there may be a general advantage in some forms of social inequality. Thus, Rawls has consistently argued that it would be irrational for persons seeking to advance their own interests to prefer a more equal distribution of resources to an unequal distribution of a larger stock that left the poorest persons better off than they would be under the scheme of equality. By this argument the principle of equal moral worth is seen to coexist with permissible inequalities in the allocation of resources or welfare in society.

Further complications stem from the notion of personality itself. It may be argued that the sense of ourselves as persons derives from the special attachments that we form to other persons, or particular places and institutions. Our sense of moral worth depends therefore on subjectively meaningful attachments that limit the extent to which we can take a general impartial concern in the interests of others. For example, if all people are of equal moral worth, it would seem that large-scale international redistribution is called for to realize the principle, but such a proposal could cut across the subjective attachments that persons form within the political communities of which they are members.

The distinctive feature of all three of these sorts of argument is that they do not simply counterpose the principle of equality to other principles of social organization, but seek instead to develop different aspects of that principle to cut the inference from equal moral worth to an equal allocation of rights and goods in society.

In response, one option is to weaken the implications of the principle of equality. For example, perhaps the principle of equal worth does not imply an equalization of rights and goods taken as a whole, but merely that there should be no discrimination in their allocation, so that relative advantages are not unfairly achieved. Similarly, it may be argued that the principle of equality merely requires that persons be given an equal opportunity to acquire unequal social and economic advantages. A particularly influential argument in this mode has been the claim that it is not social and economic inequality in itself that is objectionable, but the accumulation of social and economic inequalities across the different dimensions of social life. Related to this argument is the claim that it may be important to reduce or eliminate only certain social inequalities – in particular those that relate to access to health care or education – in order to be consistent with the principle of equal moral worth.

The most natural way to deal with this variety of interpretations is to allow that one can identify not one but a family of political positions, all of which claim to embody the principle of equal moral worth. The choice between these positions in part depends upon broader issues of social theory (for example, the extent to which one believes that inequalities in different dimensions can be kept separate) and in part depends upon the exercise of judgement (for example, the extent to which one judges that a sense of personal worth depends upon persons being able to retain the fruits of their labour as distinct from enjoying access to collectively shared rights and goods).

4 Challenges to equality

There have been a number of challenges to the moral claims of the equality principle. One familiar argument refers to the supposed disincentives to work that would be created by the practice of redistribution from the more productive to the less productive. From one point of view this can be regarded as a pragmatic question, with policy makers having to determine what the balance should be between greater productivity and greater equality. The Rawlsian difference principle, according to which inequalities should be allowed provided they raise the incomes of the least advantaged, can be interpreted here as one possible, but attractive, compromise on this question (see Rawls, J. §1).

However, the issue of incentives also raises matters of principle, since one way to avoid disincentive effects would be to adopt a scheme of taxation based not on labour but on ability. Although difficult to operate, such a scheme would in principle impose a lump-sum tax (an inherited debt) upon the more able that they would have to work to pay off. Clearly, the problem of work incentives in this case leads straight back to some of the problems of combining equality with a sense of personal attachment that were identified in the previous section.

A second principle that is often set against that of equality is the principle of merit or desert. This principle does provide a direct challenge to equality, since it requires that goods be distributed in proportion to the merits of those receiving them – with the best flute players receiving the best flutes, as Aristotle put it. However, the notion of desert is not without its own problems, and it may be argued that its application only makes sense within the context of an ongoing practice, like an orchestra with its own standards of performance, and not across society as a whole.

The final challenge to the principle of equality has come from the appeal to the notion of difference. Here the argument is that equality implies a uniformity of treatment, whereas interests in society are in fact plural. Thus, instead of basing public decision making on the principle of one person, one vote, a principle of difference would require some groups to be given a special say in certain matters of public policy, for example, women being given a veto over changes to the law on abortion.

The extent to which the appeal to difference mounts a serious challenge to the principle of equality is a matter for dispute however. Requiring equal consideration of the interests of all persons is compatible with recognizing that over some

questions the interests of certain groups are more deeply engaged than others, as can quite easily be seen in the protection of the rights of local communities to make decisions that affect them especially. Thus, to allow that there may be a special say for certain groups in matters of public policy may be compatible with the principle of equality, provided that the acknowledgement of the possibility is not unique to a particular group.

Despite these challenges, therefore, the principle of equality still remains as a central principle of modern political thought. But its very centrality means that continuing discussion over its exact interpretation and implications is likely for a long time to come.

ALBERT WEALE

ERASMUS, DESIDERIUS (*c.*1466–1536)

Although Erasmus was not a systematic philosopher, he gave a philosophical cast to many of his writings. He believed in the human capacity for self-improvement through education and in the relative preponderance of nurture over nature. Ideally, education promoted *docta pietas*, a combination of piety and learning. Erasmus' political thought is dominated by his vision of universal peace and the notions of consensus and consent, which he sees as the basis of the state. At the same time he upholds the ideal of the patriarchal prince, a godlike figure to his people, but accountable to God in turn. Erasmus' epistemology is characterized by scepticism. He advocates collating arguments on both sides of a question but suspending judgment. His scepticism does not extend to articles of faith, however. He believes in absolute knowledge through revelation and reserves calculations of probability for cases that are not settled by the authority of Scripture or the doctrinal pronouncements of the Church, the conduit of divine revelation. Erasmus' pioneering efforts as a textual critic of the Bible and his call for a reformation of the Church in its head and members brought him into conflict with conservative Catholic theologians. His support for the Reformation movement was equivocal, however. He refused to endorse the radical methods of the reformers and engaged in a polemic with Luther over the question of free will. On the whole, Erasmus was more interested in the moral and spiritual than in the doctrinal aspects of the Reformation. He promoted inner piety over the observance of rites, and disparaged scholastic speculations in favour of the *philosophia Christi* taught in the gospel. The term 'Christian humanism' best describes Erasmus' philosophy, which successfully combined Christian thought with the classical tradition revived by Renaissance humanists.

ERIKA RUMMEL

ERIUGENA, JOHANNES SCOTTUS (*c.*800–*c.*877)

Johannes Scottus Eriugena is the most important philosopher writing in Latin between Boethius and Anselm. A Christian Neoplatonist, he developed a unique synthesis between the Neoplatonic traditions of Pseudo-Dionysius and Augustine. Eriugena knew Greek, which was highly unusual in the West at that time, and his translations of Dionysius and other Greek authors provided access to a theological tradition hitherto unknown in the Latin West. From these sources, Eriugena produced an original cosmology with Nature as the first principle. Nature, the totality of all things that are and are not, includes both God and creation, and has four divisions: nature which creates and is not created, nature which creates and is created, nature which is created and does not create, and nature which is neither created nor creates. These divisions participate in the cosmic procession of creatures from God and in their return to God. As everything takes place within Nature, God is present in all four divisions. Eriugena influenced twelfth-century Neoplatonists but was condemned in the thirteenth century for teaching the identity of God and creation.

ESSENCE

See Essentialism

ESSENTIALISM

Essentialists maintain that an object's properties are not all on an equal footing: some are 'essential' to it and the rest only 'accidental'. The hard part is to explain what 'essential' means.

The essential properties of a thing are the ones it needs to possess to be the thing it is. But this can be

taken in several ways. Traditionally it was held that F is essential to x if and only if to be F is part of 'what x is', as elucidated in the definition of x. Since the 1950s, however, this definitional conception of essence has been losing ground to the modal conception: x is essentially F if and only if necessarily whatever is x has the property F; equivalently, x must be F to exist at all. A further approach conceives the essential properties of x as those which underlie and account for the bulk of its other properties.

Acceptance of some form of the essential/accidental distinction appears to be implicit in the very practice of metaphysics. For what interests the metaphysician is not just any old feature of a thing, but the properties that make it the thing it is. The essential/accidental distinction helps in other words to demarcate the subject matter of metaphysics. But it also constitutes a part of that subject matter. If objects have certain of their properties in a specially fundamental way, then this is a phenomenon of great metaphysical significance.

STEPHEN YABLO

ETERNALITY

See Eternity

ETERNITY

The distinctive, philosophically interesting concept of eternity arose very early in the history of philosophy as the concept of a mode of existence that was not only beginningless and endless but also essentially different from time. It was introduced into early Greek philosophy as the mode of existence required for fundamental reality (being) contrasted with ordinary appearance (becoming). But the concept was given its classic formulation by Boethius, who thought of eternity as God's mode of existence and defined God's eternality as 'the complete possession all at once of illimitable life'. As defined by Boethius the concept was important in medieval philosophy. The elements of the Boethian definition are life, illimitability (and hence duration), and absence of succession (or timelessness). Defined in this way, eternality is proper to an entity identifiable as a mind or a person (and in just that sense living) but existing beginninglessly, endlessly and timelessly.

Such a concept raises obvious difficulties. Some philosophers think the difficulties can be resolved, but others think that in the light of such difficulties the concept must be modified or simply rejected as incoherent. The most obvious difficulty has to do with the combination of atemporality and duration.

Special objections have arisen in connection with ascribing eternality to God. Some people have thought that an eternal being could not do anything at all, especially not in the temporal world. But the notion of an atemporal person's acting is not incoherent. Such acts as knowing necessary truths or willing that a world exist for a certain length of time are acts that themselves take no time and require no temporal location. An eternal God could engage in acts of cognition and of volition and could even do things that might seem to require a temporal location, such as answering a prayer.

The concept of God's eternality is relevant to several issues in philosophy of religion, including the apparent irreconcilability of divine omniscience with divine immutability and with human freedom.

ETHICAL NATURALISM

See Naturalism in ethics

ETHICS

1 Ethics and meta-ethics

What is ethics? First, the systems of value and custom instantiated in the lives of particular groups of human beings are described as the ethics of these groups. Philosophers may concern themselves with articulating these systems, but this is usually seen as the task of anthropology.

Second, the term is used to refer to one in particular of these systems, 'morality', which involves notions such as rightness and wrongness, guilt and shame, and so on. A central question here is how best to characterize this system. Is a moral system one with a certain function, such as to enable cooperation among individuals, or must it involve certain sentiments, such as those concerned with blame (see Morality and ethics; Moral sentiments)?

Third, 'ethics' can, within this system of morality itself, refer to actual moral principles: 'Why did you return the book?' 'It was the only ethical thing to do in the circumstances.'

Finally, ethics is that area of philosophy concerned with the study of ethics in its other senses. It is important to remember that philosophical ethics is not independent of other areas of philosophy. The answers to many ethical questions depend on answers to questions in metaphysics and other areas of human thought (see Aesthetics and ethics; Metaphysics). Furthermore, philosophers have been concerned to establish links between the ethical sphere of life itself and other spheres (see Art and morality; Law and morality). Some philosophers have, for philosophical reasons, had doubts about whether philosophy provides anyway the best approach to ethics. And even those who believe philosophy has a contribution to make may suggest that ethical justification must refer outside philosophy to common sense beliefs or real-life examples (see Moral justification).

A central task of philosophical ethics is to articulate what constitutes ethics or morality. This project is that of meta-ethics. What is it that especially constitutes the moral point of view as opposed to others? Some argue that what is morally required is equivalent to what is required by reason overall, whereas others see morality as just one source of reasons (see Normativity; Practical reason and ethics). Yet others have suggested that all reasons are self-interested, and that concern for others is ultimately irrational (see Egoism and altruism). This has not been seen to be inimical in itself to the notion of morality, however, since a moral system can be seen to benefit its participants (see Contractarianism; Decision and game theory).

The moral point of view itself is often spelled out as grounded on a conception of equal respect (see Equality). But there is some debate about how impartial morality requires us to be (see Impartiality).

Another set of issues concerns what it is that gives a being moral status, either as an object of moral concern or as an actual moral agent (see Moral agents; Responsibility). And how do our understandings of human nature impinge on our conception of morality and moral agency?

Once we have some grip on what ethics is, we can begin to ask questions about moral principles themselves. Moral principles have often been put in terms of what is required by duty, but there has been something of a reaction against this notion. Some have seen it as outdated, depending on a conception of divine law with little relevance to the modern world (see Anscombe, G.E.M.; Schopenhauer, A.); while others have reacted against it as a result of a masculine overemphasis on rules at the cost of empathy and care (see Wollstonecraft, M.).

These doubts are related to general concerns about the role principles should play in ethical thought. Situation ethicists suggest that circumstances can lead to the abandonment of any moral principle, particularists arguing that this is because it cannot be assumed that a reason that applies in one case will apply in others (see Moral particularism; Situation ethics). The casuistical tradition has employed moral principles, but on the understanding that there is no 'super-principle' to decide conflicts of principles. At the other end of the spectrum, some philosophers have sought to understand morality as itself constituted by a single principle, such as that not to lie.

Duties have been seen also as constituting only a part of morality, allowing for the possibility of heroically going beyond the call of duty (see Supererogation). This is a matter of the scope of the notion of duty within morality. There are also issues concerning the scope of moral principles more generally. Does a given moral principle apply everywhere, and at all times, or is morality somehow bounded by space or time (see Moral relativism; Universalism in ethics)? This question is related to that concerning what is going on when someone allows morality to guide them, or asserts a moral principle (see Epistemology and ethics; Moral judgment; Moral knowledge). How is the capacity of moral judgment acquired (see Murdoch, I.)? The view that humans possess a special moral sense or capacity for intuition, often identified with conscience, is still found among contemporary intuitionists (see Cudworth, R.; Hutcheson, F.; Intuitionism in ethics; Moral sense theories; Moore, G.E.; Ross, W.D.). Scepticism about the claims of morality, however, remains a common view (see Moral scepticism; Nietzsche, F.).

In recent centuries, a dichotomy has opened up between those who believe that morality is based solely on reason, and those who suggest that some nonrational component such as desire or emotion is also involved (see Hume, D.; Morality and emotions; Rationalism). Denial of pure rationalism need not lead to the giving up of morality. Much work in the twentieth century was devoted to the question whether moral judgments were best understood as beliefs (and so candidates for truth and falsity), or as disguised expressions of emotions or commands (see Emotivism; Prescriptivism). Can there be moral experts, or is each person entirely responsible for developing their own morality (see Moral expertise)? These questions have been seen as closely tied to issues concerning moral motivation itself (see Moral motivation). Moral judgments seem to motivate people, so it is tempting to think that they crucially involve a desire.

Moral principles can be understood to rest on moral values, and debate continues about how to

characterize these values and about how many evaluative assumptions are required to ground ethical claims (see Values). Against the emotivists and others, moral realists have asserted the existence of values, some identifying moral properties with those properties postulated in a fully scientific worldview (see Fact/value distinction; Moral realism; Naturalism in ethics).

2 Ethical concepts and ethical theories

Some philosophical ethics is broad and general, seeking to find general principles or explanations of morality. Much, however, focuses on analysis of notions central to ethics itself. One such notion which has been the focus of much discussion in recent years is that of autonomy (see Autonomy, ethical). The interest in self-governance sits alongside other issues concerning the self, its moral nature and its ethical relation to others (see Akrasia; Determinism and indeterminism; Evolution and ethics; Free will; Self-deception, ethics of; Will, the); and the relations of these selves in a social context (see Solidarity). Other topics discussed include the nature of moral ideals, and the notions of desert and moral responsibility (see Ideals; Moral luck).

The question of what makes for a human life that is good for the person living it has been at the heart of ethics since the Greek philosophers enquired into *eudaimonia* ('happiness') (see Aristotle; Eudaimonia; Happiness; Life, meaning of; Plato; Socrates). Once again, a philosopher's theory of the good will almost always be closely bound up with their views on other central matters (see Good, theories of the). For example, some of those who put weight on sense experience in our understanding of the world have been tempted by the view that the good consists entirely in a particular kind of experience, pleasure (see Empiricism; Pleasure). Others have claimed that there is more to life than mere pleasure, and that the good life consists in fulfilling our complex human nature. Nor have philosophers forgotten 'the bad'.

Moral philosophy, or ethics, has long been at least partly concerned with the advocacy of particular ways of living or acting. Some traditions have now declined (see Asceticism; MacIntyre, A.); but there is still a large range of views on how we should live. One central modern tradition is that of consequentialism (see Consequentialism). On this view, as it is usually understood, we are required by morality to bring about the greatest good overall (see Teleological ethics). The nature of any particular consequentialist view, therefore, depends on its view of the good. The most influential theory has been that the only good is the welfare or happiness of individual human and other animals, which, when combined with consequentialism, is utilitarianism (see Bentham, J.; Mill, J.S.; Utilitarianism).

It is commonly said that consequentialist views are based on the good, rather than on the right (see Right and good; Rights). Theories based on the right may be described as deontological (see Deontological ethics). The towering figure in the deontological tradition has been the eighteenth-century German philosopher, Immanuel Kant (see Kant, I.; Kantian ethics). Such theories will claim, for example, that we should keep a promise even if more good overall would come from breaking it, or that there are restrictions on what we can intentionally do in pursuit of the good (see Double effect, principle of; Promising).

In the second half of the twentieth century there was a reaction against some of the perceived excesses of consequentialist and deontological ethics, and a return to the ancient notion of the virtues (see Aretē; Virtue ethics; Virtues and vices). Work in this area has consisted partly in attacks on modern ethics, but also in further elaborations and analyses of the virtues and related concepts (see Love; Trust; Truthfulness).

3 Applied ethics

Philosophical ethics has always been to some degree applied to real life. Aristotle, for example, believed that there was no point in studying ethics unless it would have some beneficial effect on the way one lived one's life. But, since the 1960s, there has been a renewed interest in detailed discussion of particular issues of contemporary practical concern (see Applied ethics).

One area in which ethics has always played an important role is medicine, in particular in issues involving life and death (see Bioethics; Life and death; Medical ethics; Suicide, ethics of). Recently, partly as a result of advances in science and technology, new areas of inquiry have been explored (see Genetics and ethics; Reproduction and ethics). In addition, certain parts of medical practice which previously lacked their own distinctive ethics have now begun to develop their own.

This development is part of a wider movement involving research into the ethical requirements on those with particular occupations. Some of this research is again related to scientific advance and its implications for public policy (see Technology and ethics). But, again, attention has also been given to occupations not in the past subjected to much philosophical ethical analysis (see Business ethics; Journalism, ethics of; Professional ethics).

The planet, and those who live and will live on it, have in recent times become the focus of much

political concern, and this has had its effect on philosophy (see ANIMALS AND ETHICS; ECOLOGICAL PHILOSOPHY; ENVIRONMENTAL ETHICS; FUTURE GENERATIONS, OBLIGATIONS TO; POPULATION AND ETHICS; SUSTAINABILITY). But just as the scope of ethical inquiry has broadened, so there has been renewed interest in the specific details of human relationships, whether personal or between society, state and individual (see ECONOMICS AND ETHICS; MARKET, ETHICS OF THE; FAMILY, ETHICS AND THE; FRIENDSHIP; PATERNALISM; POLITICAL PHILOSOPHY; PORNOGRAPHY; SEXUALITY, PHILOSOPHY OF).

EUDAIMONIA

The literal sense of the Greek word *eudaimonia* is 'having a good guardian spirit': that is, the state of having an objectively desirable life, universally agreed by ancient philosophical theory and popular thought to be the supreme human good. This objective character distinguishes it from the modern concept of happiness: a subjectively satisfactory life. Much ancient theory concerns the question of what constitutes the good life: for example, whether virtue is sufficient for it, as Socrates and the Stoics held, or whether external goods are also necessary, as Aristotle maintained. Immoralists such as Thrasymachus (in Plato's *Republic*) sought to discredit morality by arguing that it prevents the achievement of *eudaimonia*, while its defenders (including Plato) argued that it is necessary and/or sufficient for *eudaimonia*. The primacy of *eudaimonia* does not, however, imply either egoism (since altruism may itself be a constituent of the good life), or consequentialism (since the good life need not be specifiable independently of the moral life). The gulf between 'eudaimonistic' and 'Kantian' theories is therefore narrower than is generally thought.

C.C.W. TAYLOR

EUTHANASIA

See LIFE AND DEATH (§§3, 4)

EVENTS

Events are entities like collisions and speeches, as opposed to things like planets and people. Many are changes, for example things being first hot and then cold. All lack a thing's full identity over time: either they are instantaneous, or they have temporal parts, like a speech's words, which stop them being wholly present at an instant; whereas things, which lack temporal parts, are wholly present throughout their lives.

Events may be identified with two types of entity: facts, like the fact that David Hume dies, corresponding to truths like 'Hume dies'; or particulars which, like things, correspond to names, for example 'Hume's death'. Which one they are taken to be affects the content of many metaphysical theories: such as that all particulars are things; that times, or causes and effects, or actions, are events; or that mental events are physical.

D.H. MELLOR

EVIL, PROBLEM OF

Introduction

In this context, 'evil' is given the widest possible scope to signify all of life's minuses. Within this range, philosophers and theologians distinguish 'moral evils' such as war, betrayal and cruelty from 'natural evils' such as earthquakes, floods and disease. Usually the inescapability of death is numbered among the greatest natural evils. The existence of broad-sense evils is obvious and spawns a variety

of problems, most prominently the practical one of how to cope with life and the existential one of what sort of meaning human life can have.

Philosophical discussion has focused on two theoretical difficulties posed for biblical theism. First, does the existence of evils show biblical theism to be logically inconsistent? Is it logically possible for an omnipotent, omniscient and perfectly good God to create a world containing evil? One classical response to this, following Leibniz, is to argue that such a God would create the best of all possible worlds, but that such a world may contain evil as an indispensable element. Alternatively, evil may be an unavoidable consequence of the boon of free will, or it may be part of a divine plan to ensure that all souls attain perfection.

The second difficulty for biblical theism is, even if we grant logical consistency, does evil (in the form, for instance, of apparently pointless suffering) nevertheless count as evidence against the existence of the Bible's God? One frequent theistic response here is to argue that the apparent pointlessness of evil may be merely a result of our limited cognitive powers; things would appear the same to us whether or not there were a point, so it is not legitimate to argue from the evidence.

1 Problems of evil

The so-called 'logical' problem of evil rests on the contention that the following two claims of biblical theism:

(I) God exists, and is essentially omnipotent, omniscient and perfectly good; and
(II) evil exists,

combine with the following plausible attribute analyses:

(P1) a perfectly good being would always eliminate evil in so far as it could;
(P2) an omniscient being would know all about evils; and
(P3) there are no limits to what an omnipotent being can do,

to form an inconsistent quintet, so that the conjunction of any four entails the denial of the fifth; most notably the conjunction of (P1)–(P3) with either of (I) or (II) entails that the other is false.

Such an argument can be taken aporetically, as a challenge to propose more subtle alternatives to (P1)–(P3), but it has usually (in analytical philosophy of religion since the 1950s) been advanced 'atheologically' as an argument against the existence of God (see Atheism; Natural theology). Also important is the distinction between the abstract problem, which takes 'evil' in (II) to refer generally to some evil or other (say the pain of a single hangnail), and the concrete problem, which construes (II) as shorthand for the existence of evils in the amounts and of the kinds and with the distribution found in the actual world. While the abstract problem raises a question of conceptual interest, it is the concrete version that gives the issue its bite.

Bold responses deny (P3), maintaining variously that God cannot overcome certain natural necessities (like Plato's Demiurge), that he cannot conquer his evil twin (as in Manichean dualism), or even that he lacks the power to compel at all (see Process theism). Some reject (P2), observing that many evils arise from free choice, while future contingents are in principle unknowable (see Omniscience). (P1) is the most obviously vulnerable because it is contrary to the common intuition that ignorance and weakness excuse, and is best replaced with:

(P4) it is logically impossible for an omniscient, omnipotent being to have a reason compatible with perfect goodness for permitting (bringing about) evils.

Rebuttals seek to counterexemplify (P4) by identifying logically possible reasons available even to an omniscient, omnipotent God.

2 Logically necessary connections with greater goods

Since omnipotence is not bound by causally necessary connections, it is natural to look for reasons among the logically necessary connections of evils with greater goods. Because the piecemeal approach of correlating distinctive sorts of good with different kinds of evil (for example, courage with danger, forgiveness with injury) threatens to be endless, it seems advantageous to identify a single comprehensive good that logically integrates all ills. One promising strategy takes its inspiration from Leibniz and develops his 'best of all possible worlds' ('BPW') theodicy in terms of contemporary possible-worlds semantics (see Leibniz, G.W. §3). If a possible world is a maximal consistent state of affairs, each of infinitely many constitutive details is

essential to the possible world of which it is a part. Assuming (P5) that possible worlds as wholes have values (P6) that can be ranked relative to one another and (P7) that the value scale has a maximum (P8) occupied by one and only one world, one can interpret divine creation in terms of actualizing a possible world and reason (P9) that necessarily an essentially omniscient, omnipotent and perfectly good God would actualize the best. Given the further controversial claim that:

(P10) the BPW contains instances of evil as logically indispensable components,

it follows that the desire to create the BPW is a reason compossible with perfect goodness for God not to prevent or eliminate all instances of evil.

(P10) contradicts our *prima facie* intuition that the BPW should be homogeneously good. Defenders of BPW approaches distinguish two ways in which value-parts may be related to value-wholes. The one presupposed by the critics is simply additive: negatively and positively valued parts simply 'balance off' one another and the inclusion of any 'minuses' inevitably lowers the value total. By contrast, parts may be integrated into wholes by relations of organic unity, in such a way that the positive value of the whole may defeat the negative value of the part (for example, the way the beauty of Monet's design defeats the ugliness of some colour patches). (P10) envisages the defeat of evil within the context of the possible world as a whole.

Leibniz thought he could prove the necessity of (P10) on the basis of his a priori arguments for the necessity of (I) and (P9); he believed that (P10) followed from the fact that God had actualized this world. Yet (P10) seems to fall into that class of propositions that are logically possible if and only if logically necessary. Those who recognize no sound demonstrations of (I) are left to claim that (P10) is epistemically possible. Since the atheologian is in the same epistemic predicament with respect to (P10), this epistemic defence would be sufficient *ceteris paribus* to discharge the burden of proof imposed on the theist by the argument from evil.

This BPW approach makes several other debatable value-theory assumptions. Augustine's notion (*contra* P8) that many alternative worlds have maximum value imposes no damage. Aquinas' insistence (*contra* P7) that for every collection of creatures there is a better one would not be crippling if every possible world above a certain value-level included evil. The rejection of (P5) and (P6), however, would be fatal for BPW approaches. Some question whether our comparative evaluations of small-scale states of affairs (for example, Jones' enjoying a symphony as better than his experiencing excruciating pain) is good evidence that the values of maximal states of affairs form a hierarchy. More fundamentally, some have argued (*contra* P5) that states of affairs are not intrinsically good or bad, although they can be good or bad for certain persons or projects and can ground different moral evaluations by particular agents. Anti-consequentialists in ethics also challenge whether (P9) follows from (P5)–(P8) (see CONSEQUENTIALISM). Deontologists would let justice to individuals trump putative increases in the value of states of affairs (see DEONTOLOGICAL ETHICS). Could creating the BPW be a reason compossible with perfect goodness for permitting suffering and degradation for the relatively innocent? Even if such value-maximizing were compatible with perfect goodness, it is not obviously required. For example, divine goodness is often interpreted as grace, a disposition to show favour independently of merit.

Finally, this modified Leibnizian approach entails divine determinism, because in choosing which of infinitely many fully determinate possible worlds to actualize, God is deciding on each and every detail. Some find this theologically objectionable, either because it seems incongruous for God to hold created persons responsible to himself for actions he determined, or because it fails to put enough distance between evil and divine aims.

3 Free-will defences

The last-mentioned worries are well accommodated by the other main traditional theme – that (some or all) evil originates in the wrong or evil choices of free creatures. Free-will approaches contend that:

(A1) created free will is a very great good, whether intrinsically or as a necessary means to God's central purposes in creation;
(A2) God cannot fulfil his purposes for and with free creatures without accepting the possibility that some will misuse their freedom, thereby introducing evil into the world.

In classical developments of this defence, (A1) is supposed to be a reason compossible with perfect goodness for making free creatures, while (A2) is compatible with the claim that evil is not necessary to the perfection of the universe or any other divine purpose. Some or all evil is not something God causes or does, but something he allows, a (perhaps) known but unintended side effect of his aims. The introduction of evil into the world is explained by the doctrine of 'the Fall', according to which God made angelic and human free agents in naturally optimal condition and placed them in utopian environments. God wanted them freely to choose what is right or good, but some angels and the

primordial humans Adam and Eve chose what is wrong, thereby actualizing the possibility of evil.

Contemporary attention (beginning with Plantinga) has turned away from free-will defences based on the principles of double effect and doing–allowing – the principle that agents are not as responsible for the known but unintended side effects of their actions as they are for their chosen means and ends; that they are not as responsible for what they allow as for what they do – to others that reconnect with possible-worlds semantics (see DOUBLE EFFECT, PRINCIPLE OF). Once again, God creates by actualizing a possible world, but freedom is now taken to be incompatible with determinism, with the consequence that God and free creatures collaborate in determining which possible world becomes actual. Created freedom does not so much 'distance' God from evils as limit which worlds God can create. As with BPW approaches, God evaluates possible worlds as to their global features – (P5) and (P6) are assumed true, although not necessarily (P7) and (P8) – but this time he evaluates those that are a function of created incompatibilist-free choice: for example, a very good world with the optimal balance of created moral goodness over moral evil.

In defence of (A2), both classical and possible-worlds approaches appeal first to the notion that not even God can cause someone else's incompatibilist-free choices. To the objection that God should use his foreknowledge to actualize only incompatibilist-free creatures who will never sin, free-will defenders reply that such foreknowledge is not prior in the order of explanation to God's decision to create. To the suggestion that God should use his middle knowledge of what free creatures would do in particular circumstances, some (notably Plantinga 1974) grant that such counterfactuals of freedom can be true, but argue that it is logically possible that all incompatibilist-free creatures be 'transworld depraved' – that is, that no matter which combinations of individuals and circumstances God actualized, each would go wrong at least once – and logically possible that any world containing as much moral goodness as the actual world would also include at least as much moral evil as the actual world contains. Thus, it is logically possible that God could not create a world with a better balance of moral good over moral evil – which would be a reason compossible with perfect goodness for his not doing so.

This ingenious argument is controverted both by those who agree and those who deny that counterfactuals of freedom can be true. Among the former, SUÁREZ defends middle knowledge but arguably finds transworld depravity impossible because of God's necessary resourcefulness, which he takes to have the following implication: necessarily, for any possible person and any situation in which they can exist, there are some helps of grace that would (should God supply them) win the creature over without compromising its incompatibilist freedom. Others (notably R.M. Adams) wonder what could make such counterfactuals true about creatures considered as merely possible. Incompatibilist freedom rules out divine choices or any native features of the creative will. To appeal to a contingent condition (*habitudo*, or primitive property) independent of both is too close for comfort to the ancient doctrine of fate that falls alike on the gods and their creatures, and contradicts traditional Christian views of divine providence. To maintain that counterfactuals of freedom are true although there is nothing to make them true violates a correspondence theory of truth (see TRUTH, CORRESPONDENCE THEORY OF). Denying truth to such counterfactuals of freedom does not automatically put (A2) clear of the objection from omniscience, however, if God could know about merely possible creatures what they probably would do in any given circumstance. But the meaning and ground of such probability assessments is at least as problematic as that of the original counterfactuals.

Even if (A2) were unproblematic, it could still be asked whether (A1) necessarily constitutes a reason compossible with perfect goodness for allowing evils. Two dimensions of divine goodness may be distinguished: 'global' goodness and goodness to individual created persons. The possible-worlds approaches cite global features – 'the best of all possible worlds', 'a world a more perfect than which is impossible', 'a world exhibiting a perfect balance of retributive justice', 'a world with as favourable a balance as God can get of created moral good over moral evil' – by way of producing some generic and comprehensive reason for allowing evil. But worlds with evils in the amounts and of the kind and with the distribution found in the actual world contain horrendous evils – evils the participation in (the doing or suffering of) which gives one *prima facie* reason to doubt whether one's life could (given their inclusion in it) be a great good to one on the whole – unevenly distributed among humans and uncorrelated with variations in desert. Even if horrors thus apportioned were epistemically compatible with global perfections, these defences of divine goodness as a producer of global perfection would not so much guarantee as raise doubts about God's goodness to individual participants in horrors. Divine goodness to them would require God to defeat the disvalue of horrors not only within the context of the world as a whole, but also within the framework of the individual participant's life. Nor will precise individual retribution fit this bill where the perpetrators of horrors are concerned. 'Balancing'

horror with horror only deepens the difficulty. Some Christians bite this bullet, insisting that decisive defeat of evil is promised only to the obedient, while the wicked can expect the reverse, a decisive defeat of positive meaning in their lives in the form of eternal damnation. Others insist that the doctrine of hell only makes matters worse by giving rise to a specialized version of the problem of evil (see HELL).

4 Divine goodness to creatures

Soul-making theodicies try to fill the explanatory gap regarding divine goodness to individual created persons by adding further hypotheses as to what they might get out of existence in an environment in which they are so vulnerable to sin, suffering and horrors. Some versions stipulate:

(A3) God's purpose in creation culminates in a process of spiritual development in which autonomous created persons with their own free participation are perfected, and transformed from self-centred to other-centred, God-centred, Christlike or otherwise virtuous souls; and

(A4) environmental evils are permitted because they create an environment favourable to soul-making.

(A3) is compatible both with the notion that humans are initially created with mature unobstructed agency and so are fully responsible for their choices, and with the alternative idea (retrieved from Irenaeus by Hick (1966)) that human agency began immature, so that sin was to be expected in the course of the 'growing-up' process. The idea is that life in a world with evils such as this is, or with created cooperation can be, 'good for the soul'.

Establishing (A4) is difficult thrice over because: (i) the task shatters into piecemeal cataloguing, with separate demonstrations for each sub-type of environmental evil; (ii) relevant necessary connections with the soul-making environment can be hard to show; and (iii) experience makes it *prima facie* implausible that a world with evils such as ours is a good classroom for the soul. In response to (ii), some (notably Hick 1966) ingeniously contend that 'dysteleological' evils lend an air of mystery which is itself favourable to soul-making. Others modify (A4) to acknowledge that some environmental evils are consequences of sin.

Where God's soul-making purpose succeeds, it is easy to see how the painful journey is worth the individual's while. What about where it fails? Some reply that the dignity of self-determination is enough, whatever the outcome. The credibility of this contention varies with one's estimate of the robustness of human nature as well as one's conception of the natural or punitive consequences of repeated bad choices. Pessimists argue that ante-mortem participation in horrors makes a mockery of human self-determination; *a fortiori*, so does decisive personal ruin in hell.

Others (notably Hick 1966) embrace a doctrine of universal salvation: if ante-mortem horrors remain undefeated between birth and the grave, education will continue after death, probably in a series of careers, until the soul is perfected and brought into intimacy with God. Thus, God does guarantee each created person an overall existence that is a great good to them on the whole, one in which participation in horrors is balanced by the incommensurate goodness of intimacy with God. Are such horrors likewise defeated within the context of the individual's existence? The stout of heart might say 'yes', because participation in horrors that remain undefeated within the individual's ante-mortem career contributes to the sense of mystery that makes a positive contribution to the soul-making of others. Since one is at least the agent-cause of the willy-nilly sacrifice of one's ante-mortem good, participation in horrors would constitute some sort of shift from self- to other- or God-centredness after all. Even if this putative positive dimension of participation in horrors is swamped by its negative aspect when considered within the framework of the individual's ante-mortem career, it provides a means for participation in horrors to be integrated into the overall development that gives positive meaning to the individual's life and thus which are defeated within the context of the individual's existence as a whole.

Some (notably M.M. Adams) contend, on the contrary, that divine goodness to created persons would do more to lend positive meaning to any careers in which they participate in horrors. The sacrifice involved in participation in horrors is pedagogically inept as a first lesson because it can damage the person so much as to make much further ante-mortem progress from self- to other- or God-centredness virtually impossible. This combines with the delay in gratification to another or perhaps many lives later to de-emphasize the importance of this life, leaving the impression that it would have been better skipped by those whose spiritual development was significantly set back through participation in horrors. To give this life, or any career involving participation in horrors, positive significance, some parameter of positive meaning other than contribution to soul-making must be found. Given two further assumptions – that divine metaphysical goodness is infinite, and that intimacy with God is incommensurably good for created persons – the mystical literature suggests

several ways for participation in horrors to be integrated into the created person's relationship with God, ranging from divine gratitude for one's earthly career to various types of mystical identification between God and creatures in the midst of horrors. Because the identification occurs in this life and divine gratitude is for this life, they add positive significance to this life even where the creature has no ante-mortem but only postmortem recognition of these facts.

5 Methodological notes

Much contemporary discussion of BPW and free-will defences has addressed itself to the logical problem of evil because we seem epistemically in a better position to assess the compossibility of logically possible reasons with various conceptions of perfect goodness than to pronounce on what God's actual reasons are. In identifying logically possible defeaters, many of the earlier discussions confine themselves to a religion-neutral value theory, the better to answer the atheologian on their own turf. By contrast, soul-making, mystical and other explanatory theodicies draw on the resources of revelation for their speculations about God's actual reasons for the evils of this world and usually address their remarks in the first instance to the believing community. The distinction between these approaches blurs when attention is riveted on the concrete logical problem of evil – that is, on the logical compossibility of God with evils in the amounts and of the kinds and with the distribution found in the actual world. In so far as the consistency of actual religious belief is at stake, it becomes highly relevant to test the reasons supplied by revelation for logical compossibility with the existence of evils and the goodness of God. Where they pass, they can be advanced as solving the concrete logical problem of evil, whether or not their truth can be proved to the atheologian.

Once the wider resources of the religions under attack are allowed to interpret (I) and (II), it becomes clear that explanatory reasons come in two broad types: reasons why God causes or permits evils, and does not prevent or eliminate them; and explanations as to how God could be good to created persons despite their participation in evil. Reasons-why identify some great-enough good with which evils are necessarily connected, while reasons-how specify ways God could defeat evils in which the created person has participated and thus give that person a life that is a great good to them on the whole. Much philosophical discussion (Swinburne is particularly insistent on this point) presupposes that the problem cannot be solved without sufficient reasons-why. The criticized religions arguably take a mixed approach. Assuming that what perfect goodness can permit or cause is a function of what it can defeat, they combine partial reasons-why with elaborate scenarios by which God defeats even the worst horrors.

6 The evidential problem of evil

Recently many philosophers (notably Rowe, Alston, van Inwagen and Wykstra) have concluded that the most serious version of the problem of evil concerns not the logical but the evidential relation between (I) and (II). The mere logical possibility that a student has broken all four limbs and been hospitalized for a heart attack will win them no extension of essay deadlines if the tutor can see that the student is in fact physically sound. Likewise, the evidential argument contends, many actual evils – such as the slow, painful death of a fawn severely burned in a forest fire started by lightning – appear pointless, in the sense that our composite empirical evidence constitutes strong reason to believe they have no point. But an omniscient, omnipotent being could have prevented some of them, while a perfectly good being would not allow or cause any of them it could avoid. Therefore, (II) concretely construed constitutes decisive evidence against (I).

Once again, replies could take the piecemeal approach, trying to show for each type of very intense suffering that it has a discernible point after all. It would not be necessary to complete the process to undermine the evidential argument. Success with some important cases would increase the probability that defeating goods are also present in other cases where we have not discovered any.

The favourite response (for example, by Wykstra, Alston and van Inwagen) attacks the argument at its epistemological foundations. The contention is that our composite empirical evidence could constitute strong reason to believe some actual evils pointless only if our cognitive powers would afford access to any point such evils might have were they to have one. If things would seem roughly the same to us (that is, if our evidence would be roughly the same) whether or not such evils had a point, the fact that we detect no point is not good evidence that there is no point. In particular, we are in no position to see that many instances of intense suffering are not explained by some of the reasons appealed to in traditional theodicies.

Defenders of the evidential argument (notably Rowe) grant the appeal of the underlying evidential principle, but relocate the disagreement in the richness of the theological hypothesis on which one draws. They argue that if one restricts oneself to a straightforward philosophical reading of (I), then it is likely that the situation with regard to intense

suffering would be different in ways discernible by us. Expanded theism might import assumptions about the hiddenness of divine providence, mystical identification with suffering creatures, etc., but deploying these resources in the evidential debate carries a cost, because the prior probability of expanded theism is lower than that of (I).

This last point holds only if the richer theological theory is advanced as true. If instead it is used, as with the logical problem, to generate possible – this time not merely logically but epistemically possible – explanations, then no dilution in prior probabilities need be accepted. And once again, the more epistemically possible explanations there are, the greater the probability that the suffering in question is not pointless.

EVOLUTION AND ETHICS

The fact that human beings are a product of biological evolution has been thought to impinge on the study of ethics in two quite different ways. First, evolutionary ideas may help account for why people have the ethical thoughts and feelings they do. Second, evolutionary ideas may help illuminate which normative ethical claims, if any, are true or right or correct. These twin tasks – explanation and justification – may each be subdivided. Evolutionary considerations may be relevant to explaining elements of morality that are culturally universal; they also may help explain why individuals or societies differ in the ethics they espouse. With respect to the question of justification, evolutionary considerations have sometimes been cited to show that ethics is an elaborate illusion – that is, to defend versions of ethical subjectivism and emotivism. However, evolutionary considerations also have been invoked to justify ethical norms. Although there is no conflict between using evolution both to explain traits that are universal and to explain traits that vary, it is not consistent to claim both that evolution unmasks ethics *and* justifies particular ethical norms.

ELLIOTT SOBER

EVOLUTION, THEORY OF

The biological theory of evolution advances the view that the variety and forms of life on earth are the result of descent with modification from the earliest forms of life. Evolutionary theory does not attempt to explain the origin of life itself, that is, how the earliest forms of life came to exist, nor does it apply to the history of changes of the non-biological parts of the universe, which are also often described as 'evolutionary'. The mechanisms of natural selection, mutation and speciation are used in evolutionary theory to explain the relations and characteristics of all life forms. Modern evolutionary theory explains a wide range of natural phenomena, including the deep resemblances among organisms, the diversity of life forms, organisms' possession of vestigial organs and the good fit or 'adaptedness' between organisms and their environment.

Often summarized as 'survival of the fittest', the *mechanism of natural selection* actually includes several distinct processes. There must be variation in traits among the members of a population; these traits must be passed on from parents to offspring; and the different traits must confer differential advantage for reproducing successfully in that environment. Because evidence for each of these processes can be gathered independently of the evolutionary claim, natural selection scenarios are robustly testable. When a trait in a population has arisen because it was directly selected in this fashion, it is called an *adaptation*.

Genetic mutation is the originating source of variation, and selection processes shape that variation into adaptive forms; random genetic drift and various levels and forms of selection dynamic developed by geneticists have been integrated into a general theory of evolutionary change that encompasses natural selection and genetic mutation as complementary processes. Detailed ecological studies are used to provide evidence for selection scenarios involving the evolution of species in the wild.

Evolutionary theory is supported by an unusually wide range of scientific evidence, gaining its support from fields as diverse as geology, embryology, molecular genetics, palaeontology, climatology and functional morphology. Because of tensions between an evolutionary view of *homo sapiens* and some religious beliefs, evolutionary theory has

remained controversial in the public sphere far longer than no less well-supported scientific theories from other sciences.

ELISABETH A. LLOYD

EXISTENCE

Philosophical problems concerning existence fall under two main headings: 'What is existence?' and 'What things exist?'. The difficulty lies in separating these questions.

The question 'What is existence?' has produced a surprising variety of answers. Some hold that existence is a property that every individual has, others that it is a characteristic that some individuals have but other (for example, imaginary) individuals lack, while proponents of the thesis that 'existence is not a predicate' hold that existence is not a property or characteristic of individuals at all.

Other philosophical issues concerning existence include: disputes about whether there are abstract objects (for example, numbers, universals) as well as concrete ones, immaterial souls as well as bodies, possible objects as well as actual ones, and so on; and questions about which entities (if any) are the fundamental constituents of reality.

PENELOPE MACKIE

EXISTENTIALISM

Introduction

The term 'existentialism' is sometimes reserved for the works of Jean-Paul Sartre, who used it to refer to his own philosophy in the 1940s. But it is more often used as a general name for a number of thinkers of the nineteenth and twentieth centuries who made the concrete individual central to their thought. Existentialism in this broader sense arose as a backlash against philosophical and scientific systems that treat all particulars, including humans, as members of a genus or instances of universal laws. It claims that our own existence as unique individuals in concrete situations cannot be grasped adequately in such theories, and that systems of this sort conceal from us the highly personal task of trying to achieve self-fulfilment in our lives. Existentialists therefore start out with a detailed description of the self as an 'existing individual', understood as an agent involved in a specific social and historical world. One of their chief aims is to understand how the individual can achieve the richest and most fulfilling life in the modern world.

Existentialists hold widely differing views about human existence, but there are a number of recurring themes in their writings. First, existentialists hold that humans have no pregiven purpose or essence laid out for them by God or by nature; it is up to each one of us to decide who and what we are through our own actions. This is the point of Sartre's definition of existentialism as the view that, for humans, 'existence precedes essence'. What this means is that we first simply *exist* – find ourselves born into a world not of our own choosing – and it is then up to each of us to define our own identity or essential characteristics in the course of what we do in living out our lives. Thus, our essence (our set of defining traits) is chosen, not given.

Second, existentialists hold that people decide their own fates and are responsible for what they make of their lives. Humans have free will in the sense that, no matter what social and biological factors influence their decisions, they can reflect on those conditions, decide what they mean, and then make their own choices as to how to handle those factors in acting in the world. Because we are self-creating or self-fashioning beings in this sense, we have full responsibility for what we make of our lives.

Finally, existentialists are concerned with identifying the most authentic and fulfilling way of life possible for individuals. In their view, most of us tend to conform to the ways of living of the 'herd': we feel we are doing well if we do what 'one' does in familiar social situations. In this respect, our lives are said to be 'inauthentic', not really our own. To become authentic, according to this view, an individual must take over their own existence with clarity and intensity. Such a transformation is made possible by such profound emotional experiences as anxiety or the experience of existential guilt. When we face up to what is revealed in such experiences, existentialists claim, we will have a clearer grasp of what is at stake in life, and we will be able to become more committed and integrated individuals.

1 Historical development

Although such earlier thinkers as Augustine, Montaigne, Shakespeare and Pascal have been called

existentialists, the term should be reserved for a loosely connected group of thinkers in recent times who were responding to certain views that became widespread in the nineteenth century. These views include, first, the scientific picture of reality as a meaningless, value-free collection of material objects in causal interactions, and second, the modern sense of society as an artificial construct that is inevitably in conflict with the aspirations of the individual. German Idealism had attempted to counteract the implications of these new ideas, but idealism had collapsed by the 1840s, and the result was a growing feeling that the individual is ultimately alone and unsupported in a cold and meaningless universe (see IDEALISM).

Existentialism appeared in the nineteenth century alongside romanticism, but it was different from romanticism in important respects. For one thing, where romanticism tried to evoke a sense of the individual's participation in the larger context of nature, the first great existentialist, Søren KIERKEGAARD, held that humans are at the most basic level solitary, 'existing individuals' with no real connections to anything in this world. Instead of suggesting that we are at home in this world, Kierkegaard tried to intensify the individual's feeling of anxiety and despair in order to bring about a 'leap of faith' that would bring the person into a defining relationship to the God-man (Christ).

The next figure usually included in the pantheon of existentialists, Friedrich NIETZSCHE, began from the assumption that the development of science and critical thinking in Western history has led to the result that people have lost the ability to believe in a transcendent basis for values and belief. When Nietzsche said that 'God is dead', he meant that all the things people previously thought of as absolutes – the cosmic order, Platonic Forms, divine will, Reason, History – have been shown to be human constructions, with no ultimate authority in telling us how to live our lives. In the face of the growing 'nihilism' that results from the death of God, Nietzsche tried to formulate a vision of a healthy form of life people can achieve once they have given up all belief in absolutes (see NIHILISM).

The translation of Kierkegaard's works and the discovery of Nietzsche's writings had an immense impact on German thought after the First World War. The psychiatrist and philosopher, Karl JASPERS, drew on these two figures to develop what he called a 'philosophy of existence'. Martin HEIDEGGER, influenced by Kierkegaard as well as by the movement called 'philosophy of life' (then associated with the names of Nietzsche, Wilhelm DILTHEY and Henri BERGSON), began his major work, *Being and Time* (1927), with an 'existential analytic' aimed at describing life from the standpoint of concrete, everyday being-in-the-world (see LEBENSPHILOSOPHIE). Heidegger's thought was also influenced by Edmund Husserl's phenomenology, an approach to philosophy that emphasizes description of our experience as it is prior to reflection and theorizing.

Working independently in France, Gabriel MARCEL was building on Bergson's philosophy to develop an alternative to the dominant idealist philosophy taught in the universities. Basing his reflections on his own experience of life, Marcel claimed that a human being must be understood as an embodied existence bound up with a concrete situation. Because the body and the situation can never be completely comprehended by the intellect, Marcel sees them as part of what he calls the 'mystery'. Maurice MERLEAU-PONTY took over Marcel's notion of embodied being-in-a-situation as basic for his own existential phenomenology. Jean-Paul SARTRE also drew on Marcel's thought, but he was especially influenced by the thought of Husserl and Heidegger. It seems that the term 'existentialism' was first used by critics of Sartre, but it came to be accepted in the 1940s by Sartre and Simone de BEAUVOIR as they replied to their critics. Merleau-Ponty and Albert CAMUS were initially associated with the movement called existentialism during its heyday after the Second World War, but both eventually rejected the term as they came to distance themselves from Sartre due to political differences.

There have been important developments outside Germany and France. The Spanish philosopher, José ORTEGA Y GASSET, influenced by Dilthey's philosophy of life, developed a number of ideas that closely parallel those of Heidegger and other existentialist thinkers. The novels and short stories of the Russian writer, Fëdor DOSTOEVSKII, were influential not only for Russian existentialists like Nikolai BERDIAEV, but for Heidegger, Sartre and Camus as well. Existentialism has also had a profound impact on other fields. The movement of existential theology remains influential today (see EXISTENTIALIST THEOLOGY), and existential psychoanalysis (especially Ludwig Binswanger, Medard Boss and Rollo May) continues to be of interest in psychotherapy. Though existentialism is no longer a central movement in philosophy, many of its principal exponents continue to be important in current philosophical discussions.

2 The human condition

Existentialists start out from the assumption that it is no longer possible to believe that there is some transcendent justification or underlying ground for

our existence. If God is dead, then we find ourselves 'abandoned', 'forlorn', 'thrown' into a world, with no pregiven direction or legitimation. Though we seek some overarching meaning and purpose for our lives, we have to face the fact that there is no 'proper function of humans' or 'plan in God's mind' that tells us the right way to be human.

This picture of our predicament leads to a particular view of human existence that is accepted by many existentialists. In contrast to traditional theories, which think of a human as a thing or object of some sort (whether a mind or a body or some combination of the two), existentialists characterize human existence as involving a deep tension or conflict between two different aspects of our being. On the one hand, we are organisms among other living beings, creatures with specific needs and drives, who operate at the level of sensation and desire in dealing with the present. At this level, we are not much different from other animals. On the other hand, there is a crucial respect in which we differ from other organisms. One way to describe this difference is to say that, because we are capable of self-awareness, we are able to reflect on our own desires and evaluate ourselves in terms of some larger vision of what our lives are adding up to. In this sense we transcend our own being as mere things. What is characteristic of our being as humans is that we *care* about the kinds of beings we are, and we therefore take a stand on our basic desires. According to the existentialists, humans are unique among entities in that they form second-order desires about their first-order desires, and they therefore have aspirations that go beyond the immediacy of their sensual lives.

Heidegger and Sartre try to capture this reflexive dimension of human existence by saying that what is unique about humans is that their own being is 'in question' or 'at issue' for them. What kind of person I am matters to me, and because I am concerned about what I am and will be, I take some concrete *stand* on my life by assuming roles and developing a specific character through my actions. But this means that my existence is characterized by a fundamental tension or clash between my immediate sensations and desires on the one hand, and my long-range aims and projects on the other. As Sartre puts it, a 'rift' or a 'gap' – a 'nothingness' – is introduced into the fullness of being in the universe by human existence. Because consciousness makes us more than what we are as creatures with immediate sensations and desires, Sartre says that human reality 'is not what it is and is what it is not'.

The conception of human existence as a tension also appears in Kierkegaard's description of the self. For Kierkegaard, humans are both finite and infinite, temporal and eternal, contingent and free. What defines our identity as selves is the concrete way we relate ourselves to this tension. In a similar way, Nietzsche holds that we are both creatures and creators, and we have to embrace both these dimensions of ourselves in order to be fully human. Heidegger and Sartre refer to the two aspects of the self as 'facticity' (our mere givenness) and 'transcendence' (our ability to surpass our givenness through our interpretations and aspirations). In their view, life is a continuous tension between these elements, a tension resolved only in death. Finally, Jaspers seems to have a similar conception of humans in mind when he points out the polarity between our being as an empirical consciousness-as-such and our desire to grasp the general and realize our freedom as *Existenz*.

If we regard the self as a tension or struggle, it is natural to think of human existence not as a thing or object of some sort, but as an unfolding event or happening – the story of how the tension is dealt with. What defines my existence, according to this view, is not some set of properties that remain the same through time, but the 'event of becoming' through which I carry out the struggle to resolve the tension that defines my condition in the world. As an ongoing happening, I *am* what I make of myself throughout the course of my life as a whole. In Ortega's words, a human 'does not have a nature, but rather a history' (see Ortega y Gasset, J.). What defines my existence as an individual is the ongoing story of what I accomplish throughout my life.

To think of a human as an unfolding story suggests that human existence has a specific sort of temporal structure. We are not like rocks and cauliflowers which continue to exist through an endless sequence of 'nows'. Instead, human temporality has a kind of cumulativeness and future-directedness that is different from the enduring presence of physical things. First, our existence is directed toward the future to the extent that we are striving to realize something for our lives. Heidegger calls this element of 'futurity' our 'being-*towards*-death,' understood as a movement toward realizing our own being by achieving certain things throughout our active lives. Second, the past shows up for us as something retained and carried forward for the purposes of our future. Depending on our projects at any given time, our past actions show up for us as assets or as liabilities in relation to what we are doing. Finally, our present appears as a point of intersection between our future projects and our past accomplishments. Because we are time-binding beings whose lives always reach out into the future and hold on to the past, we can never achieve the

kind of direct presence of self to self that Descartes thought he had found in the *Cogito* ('I think').

To say that human temporality is cumulative is to say that everything we do is contributing to creating our 'being' as a totality. In this sense, we *are* what we *do* in living out our lives: we define our own identity through the choices we make in dealing with the world. Because there is no fixed essential nature which we have in advance, our 'essence' as individuals is defined and realized through our concrete existence in the world. Whatever capacities and traits I am born with, it is up to me to take them over and make something of them in what I do. Thus, whether aware of it or not, I am creating my own identity in my actions.

3 Being-in-the-world

Existentialists are deeply suspicious of the high-level, abstract theorizing about humans found in traditional philosophy and in the sciences. In their view, the concern with subsuming all particulars under concepts and building systems tends to conceal crucial features of our lives as individuals. For this reason, existentialists generally start out from a description of ourselves as agents in everyday contexts, prior to reflection and theorizing. These descriptions reveal that it is part of our 'facticity' that we are generally caught up in the midst of things, involved with others in trying to accomplish specific goals, and affected by moods and commitments that influence our perception and thoughts. Furthermore, we are embodied beings who encounter the world only from the standpoint of a particular bodily orientation that gives us a set on things: 'I am my body' Marcel wrote, and this theme of embodiment became central to the thought of Beauvoir and Merleau-Ponty. We are also bound up with contexts of equipment in practical situations where we are trying to accomplish certain goals. Finally, as social beings, we always find ourselves embedded in a particular cultural and historical milieu that conditions our outlook and determines our basic orientation toward the world. To say that we are 'factical' beings is to say that we are always 'being-in-a-situation', where our being as selves is inseparable from a shared, meaningful life-world.

If we are always embedded in a situation, then all inquiry must start out from an 'insider's perspective' on things, that is, from a description of the world *as it appears to us* – to beings who are participants in our forms of life, with our unique sort of bodily set, feelings and modes of perception. We have no choice but to begin from where we stand in the thick of our actual lives, with our local attachments and particular cares and concerns. But this means that there is no way to achieve the sort of global 'God's-eye view' on ourselves and our world that philosophers have sought ever since Plato. Existentialists are critical of the philosophical ideal of achieving a totally detached, disinterested, disengaged 'view from nowhere' that will provide us with completely objective knowledge. The attempt to step back from our ordinary concerns in order to achieve a totally detached and dispassionate standpoint – the stance Marcel calls 'desertion' and Merleau-Ponty calls 'high-altitude thinking' – will always give us a distorted view of the world, because it bleaches out our normal sense of the significance and worth of the things we encounter around us. In order to be able to gain an insight into the way reality presents itself to us at the most basic level, then, we need to start from a description of what Heidegger calls our 'average everydayness', our ordinary, familiar ways of being absorbed in practical affairs.

The idea that our being-in-a-situation or being-in-the-world is fundamental and inescapable gives the existentialists a way of criticizing the idea, central to philosophy since Descartes, that we are at the most basic level *minds* receiving sensory inputs and processing information. Sartre, for example, rejects the idea that the self can be thought of as a 'thinking substance' or self-encapsulated 'field of consciousness' distinct from the world. In my pre-reflective activities, Sartre says, I encounter myself not as a bundle of beliefs and desires in a mental container, but as being 'out there' *with* the things I am concerned about. When I am chasing a bus, I encounter my *self* as a 'running-toward-the-bus'. My being is found not in my head, but with the bus. Sartre thinks that this follows from Husserl's view that consciousness is always 'intentional,' always directed *towards* entities in the world (see Intentionality). If Husserl is right, according to Sartre, then the 'I' is not an object, not a 'something', but is instead sheer intentional activity directed towards things in the world. The totality of my intentional acts defines me; there is no residue of 'substantial thinghood' distinct from my acts.

The existentialist conception of our irreducible being-in-a-situation calls into question some of the dualisms that have dominated so much of Western thought. First, existentialists deny the romantic distinction between an outer self – what we *do* in the world – and an inner, 'true' self that embodies our genuine nature. If we just *are* what we *do*, as existentialists contend, then there is no basis for positing a substantive 'real me' distinct from the parts I play and the things I do. Second, the account of the primacy of being-in-the-world tends to undermine the traditional subject-object model of our epistemological situation. Existentialists suggest

that the assumption that humans are, at the most basic level, subjects of experience trying to formulate beliefs about objects on the basis of their inner representations, distorts our situation. If it is true that we are initially and most basically already out there with things in the world, then there must be something wrong with traditional epistemological puzzles about how a knowing subject can 'transcend' its veil of ideas to gain knowledge of objects in the external world. Finally, the existentialist picture of our basic situation as always bound up with a practical life-world seems to raise questions about the traditional fact value distinction. Existentialists hold that we always encounter the everyday life-world as a context of equipment bound up with our aims as agents in the world. If the things we encounter are initially and most basically functional entities tied up with our purposive activities, however, then it is an illusion to think that what is given 'at first' is a collection of brute objects we subsequently invest with subjective values. In our everyday lives, fact and value are inseparable.

In general, existentialists hold that traditional dualisms arise only when we try to adopt a cool, detached, theoretical stance towards things. But since such a stance is derivative from and parasitic on a more basic way of being in which we are inseparably bound up with things in practical contexts, it cannot be regarded as providing us with a privileged insight into the way things really are.

4 Freedom and responsibility

As being-in-the-world, we are already engaged in a shared life-world that gives us a prior sense of what is possible, and we find ourselves with choices in our past that carry weight in determining how we can act in the future. This is our 'facticity', and it makes up what is just 'given' in our lives. However, existentialists regard facticity as only one aspect of human existence, for they hold that humans always have the ability to transcend their given situation by taking a stand on their own lives. As 'transcendence' we are always taking over our situations and making something of them through our choices. This ability to transcend our facticity means that we have free will. Our choices are free in the sense that (1) no outside factors determine our will, (2) in any particular case we could have acted otherwise than we did, and (3) we are therefore responsible for our choices in a way that justifies moral praise and blame (see Free will). (Nietzsche is inclined to reject the third sense because of its role in imposing feelings of guilt on people, but in other respects he seems to be committed to believing in human freedom.)

The existentialist belief in human freedom is based on a phenomenological description of our everyday lives. In confronting situations where I must make a choice, I find myself facing an open range of possible courses of action where nothing compels me to choose one course of action over the others. Even in cases where I am not aware of making choices, a moment's reflection shows that I am in fact deciding my own life. Suppose that I show up for work faithfully each day, and I believe that I am compelled to do this because I need to make money to support my family. Does this mean that I am forced to do what I do? An existentialist like Sartre would say that it is self-deception to think I am *compelled* to be a conscientious worker, for I *could* always walk away from it all and join a monastery or turn to a life of crime. If I am choosing to let considerations of duty or money be deciding factors for me in this way, then this is my choice. What this suggests is that even in my habitual and seemingly 'automatic' actions I am actually *assuming* a particular identity for myself through my own free choices, and am therefore responsible for what I do.

Sartre tries to capture this idea by saying that humans are 'condemned to be free'. Because our being is 'in question' for us, we are always taking it over and giving it some concrete shape through our actions. And this means that, whether we are aware of it or not, in continuing to act in familiar ways we are constantly renewing our decisions at every moment, for we could always change our ways of living through some radical self-transformation. Moreover, since all criteria or standards for evaluating our actions are also freely chosen, in our actions we are also deciding what sorts of reasons are going to guide our actions. With no higher tribunal for evaluating reasons for acting, we are entirely responsible for what we do: we have 'no excuses behind us nor justifications before us'.

Existentialists generally hold that we are not only responsible for the direction our own lives take, but also for the way the world around us appears. This idea has its roots in Kant's view that the reality we experience is partly shaped by the constituting activity of our own minds, though existentialists differ from Kant in holding that our construction of reality depends on our own choices (see Kant, I. §5). Kierkegaard, for example, contends that one's sense of reality is determined by the 'sphere of existence' in which one lives, so that the person who lives the life of a pleasure-loving aesthete will experience a world that is quite different from that of the duty-bound follower of the ethical. Similarly, Nietzsche holds that reality is accessible to us only through some 'perspective' or other, that there is no way to get in touch with reality as it is in itself,

independent of any point of view or framework of interpretation.

Sartre works out an especially strong version of this Kantian outlook by developing the theory of constitution in Husserl's phenomenology. Husserl held that the world we experience is constituted through the meaning-giving activity of consciousness. Sartre takes this account of constitution to mean that, because I shape the world around me through my meaning-giving activity, I am ultimately responsible for the way the world presents itself to me in my experience. Thus if I have had some painful experiences as a child, it is up to me to decide what these mean to me. I can use them as an excuse for going through life feeling cheated, or regard them as challenges that will make me stronger. Sartre's point is not that there are no constraints on the ways I interpret my situation, but that constraints and obstacles gain their meaning from me, and since there are indefinitely many possible meanings any situation can have, there is no way to identify any supposedly 'hard' facts that could be said to compel me to see things one way rather than another. But this means, according to Sartre, that in choosing my interpretation of myself, I simultaneously choose the world. It is our own freely chosen projects that determine how reality is to be carved up and how things are to count. Sartre even goes so far as to say that, if a war breaks out around me, then I am responsible for that war, because it is up to me to decide what the war is going to mean to me in my life.

Other existentialists have tried to formulate a more tempered conception of freedom. Kierkegaard argues that, because being human involves both necessity and possibility, the extreme sort of 'anything-goes' freedom (such as that later envisaged by Sartre) would lead to the 'despair of lack of necessity'. Both Heidegger and Merleau-Ponty work towards a notion of 'situated freedom' according to which choice is always embedded in and dependent upon the meaningful choices disclosed by a specific social and historical situation. Beauvoir tries to show how institutions and social practices can cut off the choices open to women and oppressed groups. Finally, Nietzsche calls attention to the way biological and historical factors operate 'behind our backs,' influencing our decisions without our awareness. But even when such limitations are recognized, the belief that we can rise above our situations to be 'creators' remains fundamental to existentialist thought.

5 Everyday existence, anxiety and guilt

Though existentialists agree that people are free to choose their own fates, they also hold that most people are quite unaware of their freedom. This obliviousness results not from ignorance or oversight, but from the fact that we usually try to avoid facing up to our responsibility for our lives. For the most part we are 'fleeing' from ourselves, throwing ourselves into mundane concerns and drifting into standardized public ways of acting. Existentialists are generally quite critical of everyday social existence. As they see it, there is a strong temptation to let ourselves get swallowed up by the 'public', the 'they', the 'herd' or the 'masses'. We try to do what 'one does' in familiar situations, and we assume that our lives are justified so long as we are following the norms and conventions laid out in our social context. In throwing ourselves into the kinds of busyness characteristic of contemporary society, we become more and more effective at finding means to achieving socially accepted ends, but at the same time we lose the ability to understand what is at stake in existing. Life then becomes a disjointed series of episodes with no real coherence or direction, and we end up dispersed and distracted, lacking any basis for meaningful action.

Existentialists give similar accounts of how social existence undermines our ability to realize ourselves as individuals. Kierkegaard describes the way that being a well adjusted member of 'the public' levels everything down to the lowest common denominator, with the result that nothing can really *count* or *matter* to people anymore. Similarly, Nietzsche describes the way that our being as 'herd' animals domesticates us and deadens our creativity, and Heidegger points out the 'tranquilization' and 'alienation from ourselves' that results from our absorption in the familiar social world. Sartre presents an especially harsh picture of social relations. Since, in his view, people can only see each other as objects and not as free beings, the Look of the Other always objectifies me and pressures me into thinking I am just a brute thing. As each individual struggles to affirm their being as a free 'transcendence' against the objectifying Look of others, the result is inevitable conflict: in the words of a character in one of Sartre's plays, 'Hell is the others'.

But many existentialists also see a positive side to social life. Though Heidegger criticizes the temptation to self-loss in our participation in the 'they', he also holds that all our possible ways of interpreting ourselves ultimately come from the social context in which we find ourselves. For this reason, becoming authentic is not a matter of escaping society, but of embracing our social existence in the right way. Marcel's attitude toward social existence shows how different he is from Sartre. He criticizes the 'technocratic attitude' of mass society not because it leads to conformism, but because it breeds an

'atomic individualism' that robs us of our deep sense of connection and obligation to others. And Jaspers and Buber both emphasize the importance of 'I–Thou' relations in realizing a full and meaningful life.

Although existentialists differ in their assessment of social existence, they agree in thinking that our ordinary, day-to-day existence is shot through with concealment and self-deception. What can free us from this distorted sense of things is not rational reflection, but a profound affective experience. This emphasis on the role of emotions or moods in giving us access to the truth about ourselves is one of the most characteristic features of existentialist thought. Kierkegaard and Heidegger, for example, focus on the disclosive role of anxiety in leading us to confront the fact that we exist as finite beings who must decide the content of our own lives. Jaspers' concept of 'limit-situations' refers to situations in which our ordinary ways of handling our lives 'founder' as we encounter certain inescapable 'antinomies' of life. For Sartre, the feeling of *nausea* shows us that it is up to us to impart a meaning to things, and *anguish* reveals our 'terrible freedom' to decide our own fates. Finally, Marcel refers to the experience of *mystery* in which we encounter that which defies our ability to gain intellectual mastery through our problem-solving skills.

Some existentialists also talk about an experience of the absurd that can come over us in our rationalistic age. Sartre claims that there are no ultimate grounds that validate our choices, so that any fundamental project we adopt must be absurd in the sense that it is ultimately unjustified. Camus' conception of the absurd is perhaps the best known of all, though it is not really representative of existentialist thought. In *The Myth of Sisyphus* (1942), he describes the feeling of futility we can experience when we become aware of the repetitiveness and pointlessness of our everyday routines and rituals. For Camus, this feeling of the absurdity of existence, a feeling in which suicide begins to seem like a real possibility, is the most fundamental experience philosophy must confront.

Finally, many existentialists point to the experience of guilt as providing an insight into our own being. Existential guilt refers to something broader than the feeling we sometimes have when we have done something wrong. In its broadest significance, existential guilt refers to the fact that there is no pregiven legitimation or justification for our existence. Though we are creatures who feel the need for some 'reason for existing', we find ourselves thrown into a world where there is no higher court of appeals that could validate our lives. We are ultimately answerable only to ourselves. In a somewhat narrower sense, existential guilt can refer to the fact that, because we are always engaged in acting in concrete situations, we are implicated in whatever happens in the world, and so we always have 'dirty hands'.

6 Authenticity

Experiences like anxiety and existential guilt are important, according to existentialists, because they reveal basic truths about our own condition as humans. Everyday life is characterized by 'inauthenticity', and in our ordinary busyness and social conformism we are refusing to take responsibility for our own lives. In throwing ourselves into socially approved activities and roles, we disown ourselves and spin a web of self-deception in trying to avoid facing up to the truth about what we are. This picture of inauthentic existence is contrasted with a vision of a way of living that does not slide into self-loss and self-deception. Such a life is (using the term found in Heidegger and Sartre) 'authentic'. Authenticity suggests the idea of being true to yourself – of owning up to who you really are. However, it is important to see that authenticity has nothing to do with the romantic ideal of getting in touch with an 'inner self' that contains one's true nature, for existentialists hold that we have no pregiven 'nature' or 'essence' distinct from what we do in the world.

If authenticity is not a matter of being true to some core of traits definitive of the 'real me', what is it? For most existentialists, becoming authentic is first of all a matter of lucidly grasping the seriousness of your own existence as an individual – the raw fact of the 'I exist' – and facing up to the task of making something of your own life. Kierkegaard, for example, holds that the only way to succeed in becoming a 'self' (understood as an 'existing individual') is by living in such a way that you have 'infinite passion' in your life. This kind of intensity is possible, he thinks, only through a total, life-defining commitment to something that gives your life an ultimate content and meaning. Nietzsche is also concerned with getting us to take hold of our own lives in a more intense and clear-sighted way. To free people from the attempt to find some overarching meaning for their lives, he proposes the idea of eternal recurrence: the idea that everything that happens in your life has happened before in exactly the same way, and will happen again and again, an endless number of times. If we accept this, Nietzsche suggests, we will be able to embrace our lives as they are, on their own terms, without regrets or dreams about how things could be different. Heidegger suggests that, in the experience of anxiety, one confronts one's own 'naked' existence as 'individualized, pure and

thrown'. As we become aware of our 'being-towards-death' in this experience, we will grasp the weightiness of our own finite lives, and we will then be able to seize on our own existence with integrity, steadiness and self-constancy.

Many existentialists agree that owning up to one's own existence requires a defining commitment that gives one's life a focus and sense of direction. For Kierkegaard, a religious thinker, self-fulfilment is possible only for the 'knight of faith', the person who has a world-defining relation to a particular being which has infinite importance (the eternal being who has existed in time, the God-man). For Heidegger, authenticity requires 'resoluteness', a commitment to some specific range of possibilities opened up by one's historical 'heritage'. The fact that the ideal of commitment or engagement appears in such widely different existentialist works raises a question about the distinction, first made by Sartre, between 'religious' and 'atheist' existentialists. Kierkegaard, Marcel and Jaspers are often grouped together as religious existentialists, yet there are profound differences in their views of the nature of religious commitment. Where Kierkegaard emphasizes the importance of relating oneself to a concrete particular, Marcel and Jaspers speak of a relation to the 'mystery' or to 'transcendence' (respectively). At the same time, so-called 'atheist' existentialists like Heidegger and Sartre tend to agree with Kierkegaard's view that being 'engaged' or having a 'fundamental project' is necessary to achieving a focused, intense, coherent life. The distinction between atheist and religious existentialists becomes harder to maintain when we realize that what is important for religious thinkers is not so much the factual properties of the object of commitment as the inner condition of faith of the committed individual. Thus, Kierkegaard says that what is crucial to faith is not the 'objective truth' about what one believes, but rather the intensity of one's commitment (the 'subjective truth').

The idea that intensity and commitment are central to being authentic is shared by all types of existentialists. Another characteristic attributed to an authentic life by most existentialists is a lucid awareness of one's own responsibility for one's choices in shaping one's life. For Sartre, authenticity involves the awareness that, because we are always free to transform our lives through our decisions, if we maintain a particular identity through time, this is because we are choosing that identity at each moment. Similarly, Kierkegaard and Heidegger talk about the need to sustain our identity at each moment through a 'repetition' of our choice of who we are. In recognizing our freedom to determine our own lives, we also come to accept our responsibility for who we are.

The notion of authenticity is supposed to give us a picture of the most fulfilling life possible for us after the 'death of God'. It calls on us to assume our own identities by embracing our lives and making something of them in our own way. It presupposes lucidity, honesty, courage, intensity, openness to the realities of one's situation and a firm awareness of one's own responsibility for one's life. But it would be wrong to think of authenticity as an *ethical* ideal as this is normally interpreted. First, becoming authentic does not imply that one adopts any particular moral code or follows any particular path: an authentic individual might be a liberal or a conservative, a duty-bound citizen or a wild-eyed revolutionary. In this respect, authenticity pertains not to *what* specific kinds of things you do, but *how* you live – it is a matter of the style of your life rather than of its concrete content. Second, in formulating their different conceptions of authenticity, many existentialists describe the ideal of authenticity in terms that suggest that it can be opposed to ethics as ordinarily understood. Kierkegaard, for example, says that it is possible that the knight of faith might have to 'transcend the ethical', and Nietzsche holds that authentic individuals will live 'beyond good and evil'. Thus, authenticity seems to have more to do with what is called the 'art of self-cultivation' than it does with ethics as traditionally understood.

7 Criticisms and prospects

Existentialism has been criticized from a number of different angles. One line of criticism holds that the emphasis on individual freedom and the rejection of absolutes in existentialism tends to undermine ethics; by suggesting that everyday life is 'absurd' and by denying the existence of fixed, binding principles for evaluating our actions, existentialists promote an 'anything-goes' view of freedom that exacerbates the nihilism already present in contemporary life. Camus' novel *The Stranger* (1942), for example, has come under attack for glorifying immoral 'gratuitous acts' as a way of affirming one's own absolute freedom. In reply, supporters of existentialism have noted that the stance portrayed in the work is not at all typical of existentialist views, and that existentialism's ideal of freedom and its sense of the need for human solidarity after the 'death of God', far from undermining ethics, might provide a very good basis for a moral point of view in the modern world.

Other critics have tried to show that the basic picture of reality presupposed by existentialism necessarily leads to nihilism. Hans Jonas argues that existentialism, despite its avowed goal of overcoming Cartesianism, tends to introduce a new kind of dualism with its sharp distinction between humans (who are thought of as absolutely

free centres of choice and action), and an inert, meaningless 'being' that is on hand for humans to interpret and transform as they please. Not only does this extreme opposition exclude animals from the realm of beings with intrinsic worth, its view of humans as thrown into an indifferent universe seems to give us freedom only at the cost of making nothing really worthy of choice.

This line of criticism is closely connected to the claim, formulated by various postmodern theorists, that existentialism is still trapped within the assumptions of Humanism, a view now supposed to have been discredited. Humanism in this context means the view, central to modern philosophers from Descartes to Kant, that the human subject is immediately present to itself as a centre of thought and action, and that the rest of the universe should be thought of as a collection of things on hand to be represented and manipulated by the subject. Postmodern theorists claim that a number of intellectual developments in the last two centuries have made it impossible to accept this picture of the centrality of the subject. The semiotic theories of SAUSSURE, for example, have shown how language tends to work behind our backs, controlling our capacities for thought and speech, and Freudian theory has shown how unconscious drives and desires lie behind many of our conscious thoughts and actions. Given these developments, it is claimed, we can no longer accept the idea that humans are capable of the sorts of self-transparency and self-determination that seem to be presupposed by existentialists like Sartre (see POSTMODERNISM).

In reply to this objection, one might point out that most existentialists have been very critical of the Cartesian belief in the transparency of consciousness to itself. Such themes as being-in-a-situation, 'thrownness', embodiment and mystery show the extent to which many existentialists think of humans as embedded in a wider context they can never totally master or comprehend. Moreover, the existentialist description of humans as temporal beings whose 'present' is always mediated by what is projected into the future and retained from the past undermines any Cartesian conception of the immediate presence of self to self in self-awareness. Finally, as Sonia Kruks argues, postmodern theorists seem to have run up against a wall in their attempts to 'de-centre the subject'. Having identified the pervasive background structures that influence the thoughts and actions of subjects, these theorists now find it difficult to give an account of the kind of critical thinking they see as central to the postmodern stance. In Kruks' view, existentialists have much to offer postmodern theory in formulating the conception of a 'situated subjectivity' that will fill this gap.

It is not clear what the future holds in store for existentialism understood as a philosophical movement. Many of the ideas that sounded so exciting in Paris in the 1940s now seem terribly old-fashioned. Many of the more viable themes in existentialism have been absorbed into new philosophical movements, especially into hermeneutics with its emphasis on humans as self-interpreting beings (see HERMENEUTICS). While some existentialist writers have faded from the scene, others have become more and more influential (though not always *as* existentialists). There has been an explosion of interest in Heidegger and Nietzsche recently, and the works of Kierkegaard, Sartre and Beauvoir are widely discussed.

Whether or not existentialism as such will continue to thrive, it seems that there will always be a place for the style of critique of society and the concern with the concrete realities of life that are central to existentialist thought. As a reactive movement, existentialism challenged the uncritical assumptions of mainstream philosophy as well as the complacency of everyday social existence. On a more positive note, it attempted to counteract the tendency to self-loss in contemporary life by formulating a vision of the kind of coherent, focused way of living that would provide a basis for meaningful action. These certainly seem to be valuable aims, and it is likely that existentialist writers will always have important contributions to make toward realizing them.

EXPERIMENT

Experiment, as a specific category of scientific activity, did not emerge until the Scientific Revolution of the seventeenth century. Seen primarily as an arbiter in theory choice, there was little, if any, analysis of experimental techniques or

the ways in which data become transformed into established facts. Philosophical analysis of experiment was typically simplistic, focusing on the role of observation alone as the foundation for experimental facts. This was challenged by Thomas Kuhn who stressed the importance of background theory and beliefs in all perception, including (its role in) scientific experiment. This interconnection between theory and experiment severely undermined the idea that experiment could stand as an independent and objective criterion for judging the merits of one theory over another.

In the 1980s new philosophical analyses of experiment began to emerge, emphasizing the ways in which experiment could be seen to have a life of its own embodying activities that could supposedly be understood without recourse to theory. Factors important in the evaluation of experimental results as well as the ways in which laboratory science differs from its theoretical counterpart became the focus for a new history and philosophy of experiment. Consequently, further debates arose regarding the relationship of experiment to theory, and whether it is possible to provide a methodological framework within which experimental practice can be evaluated.

EXPLANATION

Introduction

Philosophical reflections about explanation are common in the history of philosophy, and important proposals were made by Aristotle, Hume, Kant and Mill. But the subject came of age in the twentieth century with the provision of detailed models of scientific explanation, most notably the *covering-law* model, which takes explanations to be arguments in which a law of nature plays an essential role among the premises. In the heyday of logical empiricism, philosophers achieved a consensus on the covering-law model, but, during the 1960s and 1970s, that consensus was challenged through the recognition of four major kinds of difficulty: first, a problem about the relation between idealized arguments and the actual practice of explaining; second, the difficulty of characterizing the underlying notion of a law of nature; third, troubles in accounting for the asymmetries of explanation; and, four, recalcitrant problems in treating statistical explanations.

Appreciation of these difficulties has led to the widespread abandonment of the covering-law model, and currently there is no consensus on how to understand explanation. The main contemporary view seeks to characterize explanation in terms of causation, that is, explanations are accounts that trace the causes of the events (states, conditions) being explained. Other philosophers believe that there is no general account of explanation, and offer pragmatic theories. A third option sees explanation as consisting in the unification of the phenomena. All of these approaches have associated successes, and face particular anomalies.

Although the general character of explanation is now a subject for philosophical debate, some particular kinds of explanation seem to be relatively well understood. In particular, functional explanations in biology, which logical empiricists found puzzling, now appear to be treated quite naturally by supposing them to make tacit reference to natural selection.

1 Early history

Thinking about explanation goes back at least to Aristotle, whose discussion of four kinds of causation in the *Posterior Analytics* can properly be viewed as distinguishing modes of scientific explanation (see Aristotle §9). In the modern period, the writings of Hume, Kant and Mill offer many insights on causation, laws and regularities in nature that, sometimes explicitly, sometimes implicitly, propose doctrines about the character of scientific explanation (see Hume, D. §2; Kant, I. §§4–7; Mill, J.S. §5). However questions about scientific explanation became sharply focused in the mid-twentieth century, with the emergence of an orthodoxy about scientific explanation, which, despite its later demise, stands as one of the most significant achievements of the movement known as 'logical empiricism' (see Logical positivism §4). The writings of Karl Popper, R.B. Braithwaite, Ernest Nagel and especially C.G. Hempel, articulate an influential conception. Namely, scientific explanations are viewed as arguments in which a statement describing the fact (or regularity) to be explained is derived from premises, at least one of which is a law of nature. The underlying idea is that scientific explanations provide understanding by showing that the phenomena to be explained should be expected as a consequence of the general laws of nature.

2 The covering-law model

One important and much-discussed species of scientific explanation according with this general conception is *deductive-nomological* explanation (D-N explanation). In cases of this type, the argument is deductive, so that the statement describing the phenomenon to be explained (the *explanandum*) is a deductive consequence of the premises advanced in giving the explanation (the *explanans*). D-N explanations may be provided for explananda that describe particular facts or for explananda that announce general regularities. In the former case, there is a simple schema which exhibits the form of the explanation

$$\frac{\begin{array}{c}C_1, C_2, \ldots, C_n\\ L_1, L_2, \ldots, L_m\end{array}}{E}$$

where the statement E is the explanandum, describing the fact to be explained, the statements L_1, L_2, $\ldots$, L_m are laws of nature, and the statements C_1, C_2, $\ldots$, C_n describe particular facts (such as initial conditions). It is not hard to construct arguments that accord with this schema and which seem to explain their conclusions: derivations in classical Newtonian dynamics that deduce the trajectories of bodies from force laws and initial conditions supply many examples.

Not all explanatory arguments are deductive. The logical empiricist orthodoxy admitted *inductive-statistical* explanations (I-S explanations) as well as D-N explanations. In an I-S explanation, the explanandum is inferred inductively from premises at least one of which is a probabilistic law, for example a statement that assigns a value to the probability with which a particular trait is found among members of a specific class. Thus, to cite a famous example of Hempel's, we may explain why a child, Henrietta, contracted measles, by noting that she has been in contact with another child, Henry, who has measles, and that a large percentage of children who come into contact with measles' patients (say 99 per cent) subsequently come down with measles. Imitating the schema for D-N explanation, we can present this modest derivation as follows:

> Henrietta has been in contact with Henry, and Henry has measles.
> The frequency with which children in contact with measles' patients subsequently acquire measles is 99 per cent.
>
> (0.99)
> ____________________
> Henrietta has measles

Here, the rule indicates that the inference from premises to conclusion is inductively strong, rather than deductively valid; the figure in parentheses (0.99) reveals the strength of the inference. I-S explanations have to meet several requirements. First, the numerical strength of the inductive inference must be high (close to 1). Second, the explanans must meet a requirement of maximal specificity: there must not be known further premises which, if added to the explanans, would change the strength of the inference – as, for example, the inductive reasoning would be modified if we knew that Henrietta had received a shot for measles', and that children given such shots have a very low probability of contracting the disease.

Plainly, the explanations that scientists and others actually put forward do not look much like these stripped-down arguments. The logical empiricists claimed only that the everyday provision of explanations could be reconstructed by identifying arguments of D-N or I-S form, and that these reconstructions brought into the open what it was about the explanations that enabled them to fulfil their function. In the 1940s and 1950s, many scholars were happy to concede that the covering-law model of explanation, which assimilated explanations to arguments with laws among their premises, worked well as a reconstruction of explanations in the natural sciences – especially in physics and chemistry – but there were important debates about the application of the model to the social sciences and to explanation in everyday life. Controversy focused in particular on the activity of historical explanation. Historians construct detailed narratives that appear to explain particular events – the outbreak of the American Civil War or Henry VIII's dissolution of the monasteries. If the covering-law model is correct, then a proper reconstruction of these accounts must expose general laws. Are there indeed general laws in history? Or are the general laws that underlie historical explanation simply psychological laws that connect the motivations of historical actors with their actions (see Explanation in history and social science)?

3 Four kinds of difficulty

Troubles with history aside, the covering-law model appeared remarkably successful, a rare example of a convincing solution to a philosophical problem. Yet, in the 1960s, it came under sustained attack, and, by the end of the decade, it had been almost entirely abandoned. Four separate kinds of consideration contributed to this swift reversal of fortune.

First was a complaint, articulated by Michael Scriven, that perfectly satisfactory explanations can

be given, and understood, by people who are quite ignorant of the covering-laws that are essential to the supposed reconstruction. It is easy to explain to a friend why there is a mess on the floor by pointing out that your arm knocked the open ink bottle off the desk at which you were writing. Perhaps it would be possible for a knowing philosopher of science to cite the general laws that govern the behaviour of the bottle and the spilled ink, but this knowledge seems entirely irrelevant to the episode in which the chagrined mess-maker explains what has occurred. At the heart of Scriven's complaint lay the recognition that the covering-law model had failed to show how the idealized derivations that supposedly highlight how the explanatory work is done are adapted, in specific local situations, to transmit understanding from one person to another. Without a *pragmatics* of explanation, an account of how the ideal arguments that fit particular logical forms relate to what people actually do in giving explanations, it was possible to challenge the claim that the structures exposed by the logical empiricists reveal the crucial features that make the explanation successful.

A second difficulty resulted from continued inability to provide a satisfactory account of natural laws. From the earliest formulations of the covering-law model, its champions had insisted that not every generalization counts as a law. So-called *accidental* generalizations cannot discharge any explanatory function: it may be a timeless truth about the universe that all ball games played by a red-haired left-hander who forgoes lunch are won by the opposite team, but that accidental generalization sheds no light on the outcome of any particular game (see LAWS, NATURAL). Prior to Nelson Goodman's formulation of a cluster of difficulties surrounding counterfactuals, induction and laws, the problem of distinguishing laws from accidental generalizations appeared an interesting challenge to the logical empiricist project. Once the depth of Goodman's 'new riddle of induction' had become apparent, it seemed impossible to find a solution within the constraints that empiricists allowed themselves (see INDUCTION, EPISTEMIC ISSUES IN).

A third trouble emerged from the recognition that, even if the distinction between laws and accidental generalizations could be drawn, the covering-law model would still be too liberal. Introducing an example that was to become famous, Sylvain Bromberger pointed out that the model is blind to certain asymmetries in explanation. We can explain the length of the shadow cast by a flagpole by deriving a statement ascribing the pertinent numerical value from premises identifying the height of the pole and the angle of elevation of the sun, together with the law of the rectilinear propagation of light. This derivation fits the D-N schema beautifully. The trouble, however, is that we can produce a modified argument, according equally well with the D-N schema, by interchanging the premise that identifies the height of the pole with the conclusion: the height of the flagpole is deducible from the length of the shadow, the elevation of the sun and the law of rectilinear propagation of light. This new derivation does not seem explanatory, for it appears wrong to explain the heights of poles (or, more generally, the sizes of physical objects) in terms of the measurements of the shadows they cast. Scrupulous about appealing to causation, logical empiricism had tried to construct an account of explanation without invoking causal notions that would offend Humean sensibilities (hence, in part, the difficulty of characterizing natural laws). Bromberger's critique suggests that the omission of causal concepts assimilates cases that are importantly different: after all, it is tempting to characterize the difference between the two derivations by pointing out that the height of the flagpole *causes* the shadow to have the length it does, but that the length of the shadow does not cause the flagpole to have the height it does.

Perhaps the most influential difficulty, was the fourth, which focused on the failure of the account of statistical explanation. Alberto Coffa probed the conditions required of I-S explanation, revealing that they involved an essential reference to the state of knowledge, which made it impossible to develop a concept of a true inductive explanation. Coffa's critique complemented the work of Richard Jeffrey, who had earlier argued that it is possible to explain individual events that do not have high probability in the light of background conditions, and thus that the high probability requirement was also defective. At the same time, Wesley Salmon, in 'Statistical Explanation' (1970) worked out, in considerable detail, an account of statistical explanation that, like Jeffrey's, rejected the thesis that explanations are arguments. Central to Salmon's account was the idea that we explain by citing probabilistically relevant information. In the early versions of his model of statistical explanation, Salmon proposed that probabilistic explanations gain their force from the recognition that the probability that an individual has a property has been raised. Schematically, the information that a is F helps explain why a is G when the probability of something's being G is increased if that thing is F (more exactly: $P(G/F) > P(G)$). In this way, Salmon was able to respond to a difficulty noted earlier by Scriven – we may explain the fact that the mayor has paresis by noting that he previously had untreated syphilis,

even though the frequency with which untreated syphilitics contract paresis is small (around 15 per cent). On Salmon's account, noting that the mayor had untreated syphilis gives an enormous boost to the probability of his having paresis, raising it from the baseline figure of close to 0 to about 15 per cent.

4 Picking up the pieces

Salmon's account of explanation was deliberately motivated by the felt need to allow for explanations in the indeterministic contexts of contemporary physics. His approach dovetailed neatly with attempts, like those of Patrick Suppes, to fashion a conception of causality that would no longer be restricted to deterministic situations (see Causation; Determinism and indeterminism). From 1970 to the present, one important strand in contemporary theories of explanation has taken explanation to consist in delineating the causes of events, and has tried to honour Humean concerns about the invocation of causality by providing a theory of causation that will define causal relations in statistical terms. The simplest account of probabilistic causality would propose that A is causally relevant to B just in case $\mathrm{P}(B/A) \neq \mathrm{P}(B)$. Unfortunately, this account is too simple. As Hans Reichenbach pointed out in the 1950s the inequality will obtain when A and B are both effects of a common cause. Thus further conditions must be imposed to identify the statistical relations constitutive of probabilistic causation.

Since the 1970s a number of different proposals have competed to inherit the position of orthodoxy once occupied by the covering-law model. Most popular have been causal approaches to explanation, and, initially, proposals to ground explanation in a detailed conception of probabilistic causality promised to answer (or sidestep) the four principal difficulties outlined above. However, it has proved remarkably difficult to work out a satisfactory account of explanation along these lines, and a number of critiques, most notably that by Nancy Cartwright, have cast doubt on the viability of the enterprise. Faced with powerful objections, champions of causal approaches to explanation have pursued one of two options. One is to continue to honour Humean concerns about the causal relation, and to seek an analysis of causation that will not make use of metaphysical notions that empiricists consider dubious. The most thorough attempt to carry out this programme has been undertaken by Wesley Salmon, who has attempted to develop Reichenbach's account of causation in terms of the fundamental notion of mark transmission. The alternative approach is to declare victory by taking some causal notion as an unanalysed primitive, resisting Humean scruples about how we might know how to apply this notion as misguided (perhaps the proposals of Humphreys and Cartwright should be viewed as embodying this approach).

One evident attraction of the causal programme is that it provides an immediate response to the problem posed by the asymmetries of explanation. However, not all current theories view explanation as a matter of tracing causes. In recent years, Bas van Fraassen, Peter Achinstein and Peter Railton have all made important contributions to the pragmatics of explanation, and the first two authors have defended the view that the enterprise of seeking substantive necessary conditions that apply across all contexts in which people seek and give explanations is misguided. The danger is that such pragmatic theories of explanation reduce the enterprise to triviality. For any explanation-seeking question and any proposition we choose, it seems that we can construct a context in which that proposition is licensed as an adequate (or even a perfect) explanatory answer to that question.

A third cluster of positions stays close to the covering-law model's conception of explanations as arguments, proposing that explanatory arguments are not distinguished singly but emerge from the best way of systematizing our body of knowledge. Michael Friedman and Philip Kitcher have developed (different) accounts of explanation that take arguments to be explanatory if they belong to a system of arguments that best unifies our beliefs. One virtue of this approach is its ready provision of an analysis of theoretical explanation; its principal difficulties lie in formulating appropriate criteria for unification and for addressing the asymmetries of explanation.

The present debate echoes themes from earlier chapters in the history of philosophy. Hume's scruples about causation loom behind some efforts to articulate causal theories of explanation, those who oppose Hume on causation (like Cartwright) sometimes seem to harken back to Aristotle, and the unification approach has made an explicit connection with Kant. Perhaps these affinities suggest that contemporary debates about scientific explanation turn on larger metaphysical questions that need to be confronted directly (see Unity of science).

5 Functional explanation: a recent success story

Ironically, after the fragmentation of the consensus on the covering-law model of explanation, considerable progress has been made on studying a species of explanation that, despite careful studies by Hempel and Nagel, was always somewhat difficult

for logical empiricist orthodoxy. Biologists often appear to explain the presence of a trait or structure by identifying its function, and it is not clear how such explanations should be assimilated to a D-N (or an I-S) schema. Thanks to pioneering work by Larry Wright, contemporary philosophers of biology are largely agreed on a central idea: functional explanations are abridged versions of explanations in terms of natural selection. The identification of the function is thus seen as picking out the kind of selection pressure that causes the trait (or structure) to become originally established (or, maybe, to be maintained). The details of this idea are worked out in different ways by different authors, but the selectionist (or etiological) account of functional explanation appears to provide a philosophically satisfactory reconstruction of parts of biological practice (see EVOLUTION, THEORY OF; FUNCTIONAL EXPLANATION).

A possible moral of the comparative success in studying functional explanation is that philosophers may be too ambitious in seeking general theories of explanation. Pragmatists like van Fraassen sometimes suggest that there are many different kinds of successful explanation, and that there may be no interesting general conditions that all must meet. Perhaps the most fundamental issue confronting the theory of explanation today is whether it is reasonable to seek a theory of explanation across all contexts and all epochs or whether the study of scientific explanation should be more local, concentrating on specific types of explanation.

EXPLANATION, FUNCTIONAL

See FUNCTIONAL EXPLANATION

EXPLANATION IN HISTORY AND SOCIAL SCIENCE

Historians and social scientists explain at least two sorts of things: (a) those individual human actions that have historical or social significance, such as Stalin's decision to hold the show trials, Diocletian's division of the Roman Empire, and the Lord Chief Justice's attempt to reform the English judicial system; and (b) historical and social events and structures ('large-scale' social phenomena), such as wars, economic depressions, social customs, the class system, the family, the state, and the crime rate. Philosophical questions arise about explanations of both kinds (a) and (b).

Concerning (b), perhaps the most pressing question is whether explanations of this sort can, ultimately, be understood as merely explanations of a large number of individual human actions, that is, as a complex set of explanations of the first kind, (a).

A causal explanation is an explanation of something in terms of its event-cause(s). Some explanations under (b) appear not to be causal explanations in this sense. There are two ways in which this appears to happen. First, we sometimes seem to explain a social structure or event by giving its function or purpose. This seems to be an explanation in terms of its effects rather than by its causes. For example, it might be claimed that the explanation for a certain social custom in a tribal society is the way in which it contributes to social stability or group solidarity. An explanation of a thing in terms of its effects cannot be a causal explanation of that thing. Second, we sometimes seem to cite social structure as the explanation of something. Whatever a social structure is, it is not itself an event, and since only (it is often said) events can be causes, such a 'structural' explanation does not seem to be a causal explanation.

A second question, then, about explanations of kind (b) is whether some of them are genuinely non-causal explanations, or whether functional and/or structural explanations of this sort can be seen as special sorts of causal explanation.

Explanations of kind (a) are a proper subset of explanations of human actions generally. Although some of the discussion of these issues began life as a distinct literature within the philosophy of history, it has now been absorbed into philosophical action theory more generally. Even so, a question that remains is just which proper subset of human actions are the ones of interest to the historical and social sciences: how can we discriminate within the class of human actions between those in which historians or social scientists have a legitimate interest and those outside their purview?

F

FACTS

The existence and nature of facts is disputed. In ordinary language we often speak of facts ('that's a fact') but it is hard to take such talk seriously since it can be paraphrased away. It is better to argue for the existence of facts on the basis of three connected theoretical roles for facts. First, facts as the referents of true sentences: 'the cat sat on the mat', if true, refers to the fact that the cat sat on the mat. Second, facts as the truth-makers of true sentences: the fact that the cat sat on the mat is what makes 'the cat sat on the mat' true. Third, facts as causal relata, related in such sentences as 'Caesar died because Brutus stabbed him'. The so-called 'slingshot' argument aims to show that these roles are misconceived.

ALEX OLIVER

FACT/VALUE DISTINCTION

According to proponents of the fact/value distinction, no states of affairs in the world can be said to be values, and evaluative judgments are best understood not to be pure statements of fact. The distinction was important in twentieth-century ethics, and debate continues about the metaphysical status of value, the epistemology of value, and the best characterization of value-judgments.

ROGER CRISP

FAITH

Faith became a topic of discussion in the Western philosophical tradition on account of its prominence in the New Testament, where the having or taking up of faith is often urged by writers. The New Testament itself echoes both Hellenistic concepts of faith and older biblical traditions, specifically that of Abraham in the Book of Genesis.

The subsequent attention of philosophers has been focused primarily on three topics: the nature of faith, the connection between God's goodness and human responsibility, and the relation of faith to reason. Discussions on the nature of faith, from Aquinas to Tillich, have tried to examine the subject in terms of whether it is a particular form of knowledge, virtue, trust and so on. Regarding divine goodness, the argument has primarily focused on the relationship between faith and free will, and whether lack of faith is the responsibility of the individual or of God. Concerning the relation between faith and reason, there are two quite separate issues: the relation of faith to theorizing, and the rationality of faith. Aquinas in particular argued that faith is a necessary prerequisite for reasoning and intellectual activity, while later, John Locke explored the relationship between faith, reason and rationality, and concluded that faith can be reached through reason. This latter viewpoint was later heavily criticized by Wittgenstein and his followers.

NICHOLAS P. WOLTERSTORFF

FALLIBILISM

Fallibilism is a philosophical doctrine regarding natural science, most closely associated with Charles Sanders Peirce, which maintains that our scientific knowledge claims are invariably vulnerable and may turn out to be false. Scientific theories cannot be asserted as true categorically, but only as having some probability of being true. Fallibilists insist on our inability to attain the final and definitive truth regarding the theoretical concerns of natural science – in particular at the level of theoretical physics. At any rate, at this level of generality and precision each of our accepted beliefs may turn out to be false, and many of them will. Fallibilism does not insist on the falsity of our scientific claims but rather on their tentativity as inevitable estimates: it does not hold that knowledge is unavailable here, but rather that it is always provisional.

FALSIFICATION

See Crucial experiments; Fallibilism; Popper, Karl Raimund

FAMILY, ETHICS AND THE

Do obligations to children take priority over filial and other family obligations? Do blood kin have stronger moral claims than relatives acquired through marriage? Whatever their origin, do family obligations take precedence over obligations to friends, neighbours, fellow citizens? Do family moral ties presuppose specific family feeling, love, or loyalty? Is the traditional family of a married, heterosexual couple with biological offspring morally preferable to families formed by adoptive, single, remarried or same-sex parents, or with the help of gamete donors or gestational ('maternal') surrogates? On what grounds may friends, neighbours or government agencies intrude upon 'family privacy'?

To simplify the complexity and diversity of family life, reasoned answers to such questions may stress a single dimension. A *metaphysical* approach draws on the commands of a deity or the needs of a nation. A *biological* approach appeals to physical resemblance, blood or genes. An *economic* approach focuses on family property, income, division of work and resources, and inheritance. A related *political* approach attends to power, subordination, and rights within a family, as well as to their regulation by the state. A *psychological* approach takes affection, identification, intimacy, and emotional needs as morally decisive. A *narrative* approach makes recalling and revision of family stories the basis of moral education and the definition of family ties.

Although mutually compatible, these approaches do each tend to favour particular moral theories.

WILLIAM RUDDICK

AL-FARABI, ABU NASR (870–950)

Al-Farabi was known to the Arabs as the 'Second Master' (after Aristotle), and with good reason. It is unfortunate that his name has been overshadowed by those of later philosophers such as Ibn Sina, for al-Farabi was one of the world's great philosophers and much more original than many of his Islamic successors. A philosopher, logician and musician, he was also a major political scientist.

Al-Farabi has left us no autobiography and consequently, relatively little is known for certain about his life. His philosophical legacy, however, is large. In the arena of metaphysics he has been designated the 'Father of Islamic Neoplatonism', and while he was also saturated with Aristotelianism and certainly deploys the vocabulary of Aristotle, it is this Neoplatonic dimension which dominates much of his corpus. This is apparent in his most famous work, *al-Madina al-fadila* (The Virtuous City) which, far from being a copy or a clone of Plato's *Republic*, is imbued with the Neoplatonic concept of God. Of course, *al-Madina al-fadila* has undeniable Platonic elements but its theology, as opposed to its politics, places it outside the mainstream of pure Platonism.

In his admittedly complex theories of epistemology, al-Farabi has both an Aristotelian and Neoplatonic dimension, neither of which is totally integrated with the other. His influence was wide and extended not only to major Islamic philosophers such as Ibn Sina who came after him, and to lesser mortals such as Yahya ibn 'Adi, al-Sijistani, al-'Amiri and al-Tawhidi, but also to major thinkers of Christian medieval Europe including Thomas Aquinas.

IAN RICHARD NETTON

FASCISM

'Fascism' is a term referring both to a political ideology and to a concrete set of political movements and regimes. Its most prominent examples were the Italian and German regimes in the interwar period. Fascist ideology is sometimes portrayed as merely a mantle for political movements in search of power, but in reality it set forth a new vision of society, drawing on both left- and right-wing ideas. Fascists stressed the need for social cohesion and for strong leadership. They were more concerned to revitalize nations by cultural change than to propose institutional changes, but they saw themselves as offering a third way between capitalism and communism. There was no fascist philosophy as such, but fascist ideology drew inspiration from earlier philosophers, most notably Nietzsche and Sorel, and was supported by several contemporary philosophers, including Heidegger, Gentile and Schmitt.

ROGER EATWELL

FATALISM

'Fatalism' is sometimes used to mean the acceptance of determinism, along with a readiness to accept the consequence that there is no such thing as human freedom. The word is also often used in connection

with a theological question: whether God's supposed foreknowledge means that the future is already fixed. But it is sometimes explained very differently, as the view that human choice and action have no influence on future events, which will be as they will be whatever we think or do. On the face of it this is barely coherent, and invites the assessment that fatalism is simply an expression of resigned acceptance.

EDWARD CRAIG

FECHNER, GUSTAV THEODOR (1801–87)

Fechner was a pioneer in experimental psychology and the founder of psychophysics, the speciality within psychology devoted to quantitative studies of perception. In his foundational *Elemente der Psychophysik* (*Elements of Psychophysics*) (1860), he defined the mission of the new science to be the development of an 'exact theory of the functionally dependent relations of... the physical and the psychological worlds'. It is in this work that Fechner developed the law of sensation-magnitudes (Fechner's Law): the strength of a sensation is proportional to the logarithmic value of the intensity of the stimulus. Among his contemporaries he was well known not only for basic research in the field of electricity, but also as the author of a number of satirical works under the name 'Dr Mises'.

DANIEL N. ROBINSON

FEDERALISM AND CONFEDERALISM

Federative arrangements involve two or more governments ruling over the same territory and population. They have been of interest to political philosophers because they challenge, or at least complicate, some fundamental political concepts like authority, sovereignty, democracy and citizenship. Like citizens in actual federations, philosophers do not treat the terms of federation as a merely technocratic matter: they believe that there are morally legitimate and illegitimate ways of, among other things, dividing powers between governments, determining the representation of the subunits (for example, provinces) within federal institutions and amending the constitution. Philosophers also see in federalism a means of securing a degree of self-determination for ethnic minorities who cannot realistically expect to have their own homogeneous nation-states.

WAYNE NORMAN

FEMINISM

Introduction

Feminism is grounded on the belief that women are oppressed or disadvantaged by comparison with men, and that their oppression is in some way illegitimate or unjustified. Under the umbrella of this general characterization there are, however, many interpretations of women and their oppression, so that it is a mistake to think of feminism as a single philosophical doctrine, or as implying an agreed political programme. Just as there are diverse images of liberation, so there are a number of feminist philosophies, yoked together not so much by their particular claims or prescriptions as by their interest in a common theme.

In the earlier phases of feminism, advocates focused largely on the reform of women's social position, arguing that they should have access to education, work or civil rights. During the latter half of the twentieth century, however, feminists have become increasingly interested in the great range of social practices (including theoretical ones) through which our understandings of femininity and masculinity are created and maintained. As a result, the scope of feminist enquiry has broadened to include, for example, jurisprudence and psychoanalysis, together with many areas of philosophy.

This type of work characteristically draws on and grapples with a set of deeply-rooted historical attempts to explain the domination of women. Aristotle's claim that they are mutilated males, like the biblical account of the sin of Eve, contributed to an authoritative tradition in which the weakness, irrationality and ineducability of women, their inconstancy, inability to control their emotions and lack of moral virtue, were all regularly assumed as grounds for controlling them and excluding them from the public realm.

1 Feminism and feminisms

Throughout the history of philosophy there have been writers who challenged sexual stereotypes of women. However their works do not form a single story. It can therefore be misleading to assimilate them too quickly to the philosophical literature and political campaigns which initiated later feminist

movements, or to contemporary feminist positions. Only at the end of the eighteenth century did a stream of philosophical arguments aimed at the emancipation of women begin to gather force. Only at the end of the nineteenth century did the term *la féminisme* appear, put into circulation after the fact in France during the 1890s, and rapidly taken up in the rest of Europe and then in America. The label 'feminist' thus arose out of, and was in many ways continuous with, the sequence of nineteenth- and twentieth-century campaigns for the vote, for access to education and the professions, for the right of married women to own property and have custody of their children, for the abolition of laws about female prostitution based on the double standard, and so on. While the character and success of these movements varied from country to country (for example, women's suffrage was introduced in New Zealand in 1893, Finland in 1906 and Britain in 1928) they all drew upon, and generated, arguments about the nature and capacities of women and entertained, explicitly or implicitly, images of their liberation. Many of the most influential philosophical defences of women's emancipation dating from this period were written by people involved in political work – to name only two, John Stuart MILL, the author of *The Subjection of Women*, proposed to the British parliament in 1867 an amendment to the Reform Bill designed to give votes to women, while Emily Davies, author of *The Higher Education of Women*, was the foundress of Girton College, Cambridge, the first women's college of higher education in England.

We have no difficulty in retrospectively classifying works such as these as feminist, although this is not a description their authors would have used, because they contain analyses of women's oppression and proposals for overcoming it which mesh easily with analyses and proposals later regarded as central to the feminist cause. At the same time there are also significant divergences between feminist writers, past as well as present. Different interpretations of the disadvantages to which women are subject, allied to different conceptions of an improved distribution of power, gave rise to divergent and sometimes irreconcilable feminisms. Compare, for example, the broadly liberal view that the oppression of women consists in their lack of political equality with men and can be alleviated by giving both sexes the same political rights, with the separatist view that women's oppression lies principally in their sexual subordination to men and can only be overcome in societies that are, as far as possible, exclusively female.

Historians interested in the former are liable to focus on works such as Poulain de la Barre's *De L'Égalité des deux sexes* (1673) or MARY WOLLSTONECRAFT's *Vindication of the Rights of Women*. By contrast, writers wishing to trace the history of the latter are more likely to pick out Mary Astell's proposal that ladies should retire from the society of men who debar them from realizing the natural desire to advance and perfect their being, or Charlotte Perkins Gilman's utopia *Herland* about an isolated society of women who are able to have children without male assistance. As these examples indicate there are many feminisms, each with a history of its own.

2 Renaissance and early-modern forerunners

Although female inferiority is the dominant note that sounds through the Western philosophical tradition, its character was never a matter of consensus. Long drawn out theological debates about whether woman is a human being, whether she is made in the image of God, whether she is a perfect creation of God or an imperfect version of man, and whether men and women are equal before God, all appeal to classical authorities, to the Bible and to the Church Fathers, and rumble on through the Middle Ages and into the Renaissance. Complementing them are a series of more secular discussions, of which one of the most consistent concentrates on women's intellectual capacities. In her *Livre de la cité des dames* (1405) CHRISTINE DE PIZAN extols the advantages of educating women, a theme subsequently taken up by Renaissance writers for whom it played a part in the so-called *Querelle des Femmes* – a series of philosophically repetitive disputes about whether fidelity in marriage should be demanded of both sexes, whether and to what extent women should be educated, and whether women were entitled to the respect and gratitude of men for the services they rendered them. On one side of these debates, women's inferiority was reasserted by appeal to example, authority and reason. On the other, their superiority was defended in a variety of genres. Some authors – for example Cornelius Agrippa – employed the rhetorical device of the paradoxical encomium, attempting to surprise and impress by ingeniously reversing conventional evaluations of men and women (see AGRIPPA VON NETTESHEIM). Others drew on a well-tried stock of cases to illustrate women's superior virtue, intelligence or judiciousness. The choice of these genres strengthens the impression that, while such champions of the female cause sometimes propose limited social reforms, they are on the whole anxious not to unsettle the status quo. Their aim is to entertain – to tease men and flatter women, and perhaps in doing so to make both reconsider their roles – rather than to foment social change.

Traces of this style endured well into the seventeenth century and are visible even in writers who in other ways broke with the terms of the *querelle*. A particularly striking change is the move away from debates about the relative inferiority or superiority of women, to works purporting to show that the sexes are equal. Marie de Gournay, who claimed that she was the first to take this view, published her *Égalité des hommes et des femmes* in 1622, and the same theme was taken up with a new determination later in the century. In France, Poulain de la Barre adopted a fresh approach when he appealed to Cartesian scientific method: a clear and distinct understanding of the issue can be arrived at, he insists, by rational demonstration. Although his *De l'Égalité des deux sexes* (1673) sometimes lapses into the older style of argument – women are more decorous and discreet than men, women's work is more valuable than that of men, and so on – Poulain is remarkable for the forthright manner with which he asserts that the relations between mind and body and the capacities of the mind are the same in both sexes, and even more for the consequences he draws from this claim. There is no reason, in his view, why women should not occupy all the public roles currently held by men. Since they are capable of equalling men in understanding all the sciences (including both civil and canon law) they could, if educated, teach in the universities, be legislators, rulers, generals of armies, judges and – most radical of all – preachers and ministers of the Church.

Poulain's willingness to contemplate such dramatic social change is more unusual than his emphasis on intellectual equality or his downplaying of the significance of the bodily differences between men and women. A number of women writing in the second half of the seventeenth century criticize men for depriving them of learning and education, and imply that women are quite capable of ruling themselves, and indeed men. For instance Anna Maria von Schurman in the Netherlands, Sor Juana Ines de la Cruz in Mexico, Jacqueline Pascal and Madame de la Maintenon in France, and Bathusa Makin in England all write in favour of the education of girls. Authors such as Margaret Cavendish and Mary Astell are by turns bitter and witty in their wide-ranging critical explorations of women's subjection to men.

3 Claims of right

As early as 1673, Poulain de la Barre argued that women and men possess an equal right to knowledge, conferred on them by nature. All humans pursue happiness; no one can achieve happiness without knowledge; so everyone needs knowledge. To ensure that people are able to pursue their proper end, nature has supplied the necessary means in the form of a right. We find here the beginnings of an appeal to rights which became progressively more central until, a century or so later, it dominated debate. In the immediate wake of the French Revolution, Olymphe de Gouges presented the French Assembly with a Declaration of the Rights of Women (which it declined to ratify). Women, she argued, should have rights to employment, legal rights within the family, a right to free speech and a separate assembly in which they could represent themselves. The same theme was taken up in England by Mary Wollstonecraft, who in 1792 published *A Vindication of the Rights of Women*. Challenging Rousseau, Wollstonecraft argued that the education and emancipation of women are conditions of a truly civilized society. God has endowed all humans with reason so that they can use it to govern their passions and attain knowledge and virtue. To deprive women of the opportunity to perfect their nature and increase their capacity for happiness is to treat them as less than human and render them 'gentle, domestic brutes'. It is to trample on their rights and keep them in a state of subjection which damages both them and their male captors.

Far from being natural, Wollstonecraft explains echoing the arguments of Mary Astell, the presumed inferiority of women stems primarily from their lack of education. Cut off from learning and encouraged to care only for love and fashion, they are unable to cultivate any solid virtues, and do indeed display the flightiness and stupidity for which they are criticized. However, as well as damaging themselves, women in this condition diminish others. First, they damage men. To treat a fellow human despotically shows a lack of virtue, and just as kings are corrupted by their excessive power, so men are corrupted by the tyranny they exercise over their sisters, daughters and wives. Second, ignorant and powerless women are unfit to instil virtue into their children. 'To be a good mother – a woman must have sense and that independence of mind which few women possess who are taught to depend entirely on their husbands' (*A Vindication*).

Although Wollstonecraft's argument hinges on her claim that women are as rational as men, she has no sympathy for what she calls 'masculine women'. The aim of educating women is, in her view, to make them into virtuous wives and mothers who, by fulfilling these natural duties, will become useful members of society. Freed from male subjection, educated women would not usurp the roles of men but would freely and virtuously pursue their domestic lives to the benefit of society as a whole.

The claim that men and women are intellectual equals is here allied to the view that there are natural differences between them which fit them for distinct ways of life: rational women will see that their place is in the home.

This easy division of labour was put under increasing pressure during the nineteenth century, as feminist thinking became less concerned with women's overarching moral right to liberty and focused instead on particular legal entitlements such as the right to own property, to enter the professions, and above all to vote. Nevertheless, arguments which appeal simultaneously to the equality and difference of the sexes, and sustain the view that women excel in certain domestic virtues, remained common. The US suffragist, Elizabeth Cady Stanton, demanded the vote for women from the New York legislature during the 1850s on the grounds that 'the rights of every human being are the same and identical'. But she also argued that, if women were able to represent themselves by voting, they would make a distinctive contribution which would balance that of men.

The same wish to reconcile the demands of equality and difference is evident in John Stuart Mill's *The Subjection of Women* (1869). Mill argues that women are entitled to the same rights as men and should be able to hold public office, to work, to own property and to vote. He also argues that married women should not be required to obey their husbands and should have custody over their children. His primary ground for these conclusions is that women and men are equal, but he supplements this argument with further claims about the benefits that the freedom of women would bring. Like Wollstonecraft, he claims that the power of men over women 'perverts the whole manner of existence of the man, both as an individual and a social being', and reiterates her view that there can be no true affection between spouses who have nothing in common. It is only once women are educated that there can be the solid, enduring friendship between the sexes that heralds the moral regeneration of mankind. However, two further lines of thought appeal to assumed differences. Mill first argues that women possess a distinctive aversion to war and addiction to philanthropy, of which they would make better use if they were better informed. In addition, although women should have the right to work, Mill takes it that when they marry they make 'a choice of the management of a household, and the bringing up of a family' as the first call on their exertions. Older women who have completed this task may decide to direct their energies to public life, for instance by standing for parliament. But the first place of married women is, once again, in the home.

4 Sexual oppression and emancipation

The view that the oppression of women could be overcome once they had the same rights as men was therefore compatible with a conventional understanding of the division of male and female labour. But doubt was cast on this whole approach to emancipation by the fact that, once the vote was won, women did not on the whole use their new-found political power to press for further reform. Many suffragists were keenly disappointed, and feminists of more radical political persuasions were strengthened in their conviction that the source of women's oppression did not lie in their lack of political rights. Reforms such as the married women's property act and the right to higher education, they pointed out, benefited middle-class more than working women. More important still, the root of women's subordination lay not in their civic but in their private lives – in their roles as wives and mothers.

This latter view was partly derived from Engels' *Origins of the Family, Private Property and the State* (1884) in which he argued that women's oppression is primarily sexual. There is nothing natural about the patriarchal family. Rather, this institution came into existence at a particular point in history together with private property. To be able to hand down their property to their sons, men needed complete sexual possession of the mothers of their children, and to this end they reduced women to servitude. In capitalist society, women's subjection consists not in their lack of legal rights, but in their weak position in the labour market which in turn forces them into marriage. Women face a choice between lives of near-destitution as workers or lives of slavery as wives and mothers, or in the case of working class women, both exploitation at work and subjection in marriage. Only once capitalism is overthrown will they escape this plight and be freed from dependence.

In Russia, the predicament diagnosed by Engels was confronted by the revolutionary Alexandra Kollontai (1872–1952), who insisted in *The Social Basis of the Woman Question* (1909) that proletarian women must refuse to cooperate with the bourgeois feminist movement and attack capitalism, the source of their oppression. As Commissar of Social Welfare in the Russian Revolutionary Government of 1917, Kollontai oversaw the drafting of legal reforms designed to revolutionize the family and sexual relations between men and women and to relieve women of the 'triple load' of wage worker, housekeeper and mother. These reforms were organized around a distinction between productive and non-productive labour, and were based on the view that women should be relieved of the burden

of non-productive domestic labour (cleaning, cooking, washing, caring for clothes, and many aspects of child-rearing) to engage in productive labour alongside men. In this way they would achieve economic independence. At the same time, women's work was to take account of their productive childbearing role. The work of carrying and bringing up children was no longer to be seen as the responsibility of individual families but as a task for the state, since it was in the interest of the workers' collective that children should be born and that they should grow up to be able-bodied and good revolutionaries.

In the early years of the Bolshevik government, Kollontai began to implement a series of radical though short-lived changes. Women were to have full civil rights; civil marriage and divorce laws were introduced; legitimate and illegitimate children were to have the same legal rights; and in 1920 abortion was legalized. As far as labour was concerned, women's work was to take account of childbearing. They were not to do heavy work which might damage their health or work long hours or night shifts. They were to have paid maternity leave and health care during pregnancy. Once children were out of infancy they were to be cared for in crèches, kindergartens and schools which would also provide meals and clothing.

According to Kollontai, the dictatorship of the proletariat will abolish the family and with it bourgeois sexual morality. For though the state should, in her view, concern itself with children, it does not have any more extended interest in the relations between adults. Conventional notions of romantic love must not undermine comradeship; yet Kollontai stresses that solidarity can only exist between those who are capable of love and sympathy, and envisages a society in which people are emotionally educated to feel many forms of love for different people.

In the USA, Engels' view that women's oppression is rooted in the family was used by the anarchist, Emma Goldman (1869–1940), to ground a different set of conclusions. Access to education and work, for which emancipationists had fought so hard, produced women who were 'professional automatons' and lacked 'the essence that enriches the soul'. By entering the public sphere, women had joined an impure state which prevents both women and men from developing the inner qualities that spring from sexual intimacy and constitute freedom, but is particularly distorting for women, for whom love is even more important than it is for men. The question of how to become free is therefore a question about how to foster sexual self-expression, and Goldman is adamant that this can only happen once women cease to be the sexual possessions of their husbands. As well as eschewing the public sphere, women must reject the private institution of marriage in which, driven by economic need, they purchase financial security at the price of their independence. They must learn instead to recognize and follow what Goldman calls their instinct.

Goldman and Kollontai share with some of their liberal forebears and contemporaries the premise that an institution of marriage in which women are sexually dominated by, and economically dependent on, their husbands, makes them unfree. More radically, both claim that these evils can only be overcome by sweeping away conventional notions of marriage and family. Beyond this, however, they diverge sharply. For Kollontai, liberty consists in productive labour in which both women and men must engage if they are to be equal and equally free. In the case of women, however, productive labour can take the distinctive form of bearing children. Motherhood (women's difference), is subordinated to an overall conception of equality according to which men and women are not treated in the same way, but make the same kind of contribution by working productively. Goldman, by contrast, conceives freedom as a state of individual exploration and self-expression which needs to be pursued outside the impurity and corruption of the state and has little to do with work. Both men and women need love in order to become free, but for women, sexual intimacy plays a particularly important part in this process. While Kollontai separates reproductive sex from other erotic relations, Goldman tips the balance away from motherhood. Unconstrained love, which may or may not be the love of mothers for their children, is what enables women to fulfil themselves and become free.

5 The pervasiveness of male domination

It has become customary to distinguish a first wave of feminism, dating from the mid-nineteenth century to the 1930s, from a second wave, breaking in the 1970s. This chronology is designed to highlight the absence of specifically feminist political campaigns in the intervening period, but needs to be applied with care, since one of the most influential works of modern feminist philosophy, Simone de Beauvoir's *The Second Sex*, was published in 1949 (see Beauvoir, S. de). Dissatisfied with existing accounts of women's subordination to men, Beauvoir confronted the question 'What is Woman?' by exploring the limited answers offered by historical materialism and psychoanalysis. Both these theories, she claims, beg the question. In *The Origin of the Family*, Engels asserts that the institution of private property results in the enslavement of women, but offers no means of explaining why this

should have been so. Equally, Freud's account of sexual differentiation fails to say what previous evaluation of virility makes boys proud of their penises and makes girls attribute special significance to their lack of this bodily part. To explain women's oppression, in which women themselves are complicitous, it is not enough to appeal merely to economic categories or patterns of psychological development already imbued with the evaluations that constitute male power. What is needed is a theory capable of doing justice to the vast variety of practices that contribute to women's subordination.

To motivate her analysis, Beauvoir appeals to Hegel's diagnosis of the conflict underlying the relation between master and slave. There is 'in consciousness itself a fundamental hostility to every other consciousness; the subject can be posed only in being opposed – he sets himself up as the essential, as opposed to the other, the inessential, the object' (see HEGEL, G.W.F. §5). Somewhat as the master achieves subjectivity by vanquishing the opponent who becomes his slave, so man establishes himself as a free subject by dominating woman, who serves as his other. To put it in Sartrean terms, he becomes transcendent while she remains mired in immanence (see SARTRE, J.-P.). Yet this situation is puzzling. Like men, women are conscious beings capable of returning the male gaze; but they nevertheless allow themselves to be dominated. Why do they occupy this position? Why do they not try to dominate men? Although Beauvoir suggests that the comparative passivity of women originates in childbearing, she is mainly interested in analysing the multitude of social practices which conspire to keep women in the position of the other and prevent them from seeking their own transcendence. These practices, she argues, are sustained both by men, who encourage and reward female passivity, and by women, who cooperate in their own domination. The latter, however, is ultimately a form of slavery. To allow oneself to be treated as an object is to fail to realize one's being by making one's own choices, and to shirk the painful project of becoming free. How, then, are women to liberate themselves? Women, Beauvoir suggests, must avoid the roles of wives and mothers in which they are most easily objectified and discover themselves through work. Once they begin to exercise the assertiveness and courage essential to freedom, conceptions of what it is to be a woman will alter, and women and men will gradually find ways to treat one another as equals.

One of Beauvoir's most profound contributions to feminist philosophy lay in her insistence that women are dominated in all aspects of their lives. Their comparative lack of freedom does not consist merely in the absence of civic rights, or in particular institutions of motherhood and marriage, although these are contributory factors. Rather, they are kept in their inferior place by 'the whole of civilization' – by a multitude of evaluations and social practices (tellingly described in chapters on childhood, the young girl, sexual initiation and so on) which shape our understandings of male and female, masculine and feminine. As she indicates in her celebrated remark, 'One is not born, but rather becomes, a women', Beauvoir holds that it is through social practices that bodies come to be understood and lived as male or female, and through these same practices that the differences between them are invested with evaluative significance. Becoming a woman is a cultural and historical process which is never completed. Although Beauvoir allows that there will always be differences between women and men deriving from their bodily distinctions and the effect these have on their sensuality, she suggests that there is no one thing that women intrinsically or naturally are. Correspondingly, there is no obviously discernible limit to what they may become.

6 Second- and third-wave feminism

Many of the critical and constructive themes discussed by Beauvoir were taken up again in the late 1960s and 1970s (though often without much reference to *The Second Sex*) by a generation of women who struggled, in the light of their personal experience, to revise the social and psychological theories around which academic debate revolved. On a critical plane, they enlarged Beauvoir's objections to Marxism and psychoanalysis and added criticisms of other sociological approaches such as functionalism, sometimes engendering debates which remained lively throughout the next twenty or so years. For feminists concerned with Marxism, the key issues were whether women could be satisfactorily accommodated within a theory which focused on the class structure of society, and whether women's oppression could be adequately explained in terms of their place in the relations of production and the ideologies to which these gave rise. Studies of domestic labour and of women's sexual subordination suggested that, while Marxist analyses of women in capitalist societies remained valuable, the answer to these questions was negative. Turning their attention to psychoanalysis, a number of writers launched an influential attack on Freud's construction of femininity as a passive, masochistic, narcissistic and intellectually limited condition. Their re-reading gave feminists pause, and initiated a series of fruitful reinterpretations and modifications within psychoanalytic theory (see IRIGARAY, L.; KRISTEVA, J.).

Critical interpretations of this type were also the vehicle for a number of important innovations in feminist thinking which raised fresh questions and consolidated novel approaches. Writers such as Kate Millett and Shulamith Firestone argued in the early 1970s that the forms of domination isolated by feminists are all relatively superficial in comparison with patriarchy – the sexual power that men exercise over women, primarily within the family, but also in social, economic and political institutions. In a wide range of societies, it was pointed out, men's sexuality is the source and justification of their power, the purportedly natural characteristic that gives them the right to rule women. The workings of patriarchy are evident not just in erotic relations between the sexes, but in the manifold means by which men and women are socialized as to temperament, role and status, men being taught to regard themselves as potent and active, women to perceive themselves as subordinate and sexually impure.

Patriarchy, then, relies not so much on the biological differences between men and women as on deep-seated cultural interpretations that give them value and significance. In the early 1970s this distinction came to be regarded as crucial, and writers such as Millett and Ann Oakley took over the terms 'sex' and 'gender' to mark it: sex refers to the biological traits that make a person male or female, gender to culturally variable conceptions of masculinity and femininity. Taken together, the notions of patriarchy, sex and gender provided an Anglo-American articulation of many of the themes announced by Beauvoir, and gave rise to a series of theoretical debates, some of which are still going on. Is sex really separable from gender, or is our experience and theorizing so mediated by culture that the idea of the simply biological ceases to make sense? Is patriarchy a useful analytical category, or is it either unduly general, or unduly reductionist? How, in any case, is patriarchal power related to other forms of political and economic power? And is it really as strong and pervasive as its exponents claim?

Regardless of the fate of these questions, the belief that men's domination of women may be sustained by all sorts of practices had a vast impact on the Academy, as feminists began to take a fresh look at the texts and theories they studied professionally. This approach proved exceptionally fruitful when applied to literary texts – Simone de Beauvoir had included a study of 'The Myth of Woman in Five Authors' in *The Second Sex*, and Millett's *Sexual Politics* opens with insightful readings of Henry Miller, Norman Mailer and Jean Genet. It was soon adopted by philosophers, who started to analyse the conceptions of gender embedded in the great works of the philosophical tradition. Genevieve Lloyd's *The Man of Reason* (1984) and Carole Pateman's articles on contractarian political theory are notable early examples of this kind of work, and were rapidly followed by critical scrutinies both of the various areas of philosophy and particular positions within them (see FEMINIST EPISTEMOLOGY).

While the results of this academic flowering have been extremely diverse, a number of themes stand out. First, some impressive recent work has shown how philosophical standards and doctrines that have claimed for themselves an objective and universal status reflect particular interests, values and priorities attuned to broader conceptions of masculinity. Discussions of human beings sometimes turn out upon examination to be discussions of men, and norms that are held to apply generally sometimes turn out to apply better to men than to women. In this way, philosophy has contributed to the cultural constructions of gender that play a part in legitimating and maintaining male power. Feminist philosophers have gained insight into this phenomenon by studying the history as well as the contemporary practice of their subject, paying attention not only to the substance of an author's work but also to its literary form. In an influential series of essays translated into English in 1989, Michele le Doeuff argued that an analysis of imagery and metaphor can uncover gendered presuppositions within a text. This approach has helped us to move beyond the mere identification of sexism within the works of the great philosophers, and to arrive at an enriched understanding of the resources of the past. Although it is true that traits associated with women such as imagination or emotion have often been denigrated and marginalized within the philosophical tradition, it contains ideas and arguments which can be used to advance contemporary debates.

Feminist scholarship has also revived the writings of women philosophers and examined the processes through which these came to be neglected. For example, we are acquiring a fuller appreciation of the contribution made by women during the early modern era to natural philosophy (significant figures here are Margaret Cavendish, Anne Conway, Jeanne Dumee and Aphra Behn) and the field of morals (notably in the work of Madeleine de Scudery, Damarys Masham, Mary Astell, Catherine Trotter and Gabrielle Suchon).

As feminists have opened up new philosophical questions and lines of criticism, these have been taken up by the profession at large and absorbed into the mainstream. Analyses of the political exclusion of women have been applied in multicultural contexts; moral philosophers are less inclined to

think of reason and passion as opposites; and feminist arguments about the social character of power are increasingly reflected in epistemology and philosophy of language. To some extent, then, feminist philosophy is ceasing to occupy the role of the other, and is finding ways to converse on equal terms with advocates of the tradition from which it sprang. But it is also continuing to develop internally, and has recently trained its own critical techniques on its long-standing habit of making claims on behalf of 'women'. These purportedly universal pronouncements, it has been pointed out, fail to take account of the differences between women of diverse races, sexual orientations, nationalities or classes. Moreover, if gender is not a natural category there may be little to be said about women as such, and we need to become more sensitive to the many conceptions of femininity found in different societies. This anti-essentialism has profound implications for feminism, both as an academic preoccupation and as a political movement, and marks an important shift away from its own origins. Within philosophy, it has reopened debate about the nature and status of 'woman', the key term around which feminism revolves.

FEMINIST EPISTEMOLOGY

The impact of feminism on epistemology has been to move the question 'Whose knowledge are we talking about?' to a central place in epistemological inquiry. Hence feminist epistemologists are producing conceptions of knowledge that are quite specifically contextualized and situated, and of socially responsible epistemic agency. They have elaborated genealogical/interpretive methods, have advocated reconstructions of empiricism, have articulated standpoint positions and have demonstrated the potential of psychosocial and post-structural analyses to counter the hegemony of epistemological master narratives. In these reconfigured epistemologies, feminists have argued that the cognitive status and circumstances of the knower(s) are central among conditions for the possibility of knowledge. They have demonstrated the salience, in evaluating any epistemic event, of the social arrangements of power and privilege by which it is legitimated or discredited.

Feminists are engaged at once in critical projects of demonstrating the privilege-sustaining, androcentric character of 'the epistemological project' in most of its received forms, and in transformative projects of reconstructing methodologies and justificatory procedures so as to eradicate their oppressive, exclusionary effects. They have shown that, in late-twentieth-century Western philosophy, the circumstances of mature white men continue to generate prevailing ideals and norms of 'human nature', while the ideals of reason, objectivity and value-neutrality around which most mainstream theories of knowledge are constructed, like the knowledge they legitimate, tacitly validate affluent male experiences and values. Scientific knowledge, which is still an overwhelmingly male preserve, stands as the regulative model of objective epistemic authority; and the experiences and values of non-male, non-white and otherwise differently placed knowers typically have to accommodate themselves, Procrustean-style, to an idealized scientific and implicitly masculine norm, or risk dismissal as inconsequential, aberrant, mere opinion.

In engaging with these issues, most feminists – like many other participants in 'successor epistemology' projects – retain a realist commitment to empirical evidence, while denying that facts or experiences 'speak for themselves' and maintaining that most truths are as artefactual as they are factual. Questions of cognitive authority and answerability thus figure as prominently as issues of epistemic warrant in these projects, where feminists are concentrating less on formal, universal conditions for making and justifying knowledge 'in general' than on the specificities of knowledge construction. Hence these inquiries are often interdisciplinary, producing detailed analyses of everyday knowledge-making and of scientific or social scientific inquiry; drawing out their gendered and other locational implications. In these projects feminists are showing that avowedly engaged, politically committed investigations can yield well-warranted conclusions.

FEMINIST POLITICAL PHILOSOPHY

In all its forms, feminism asserts that social and political structures in society discriminate against women. Feminist political philosophy aims to show how traditional political philosophy is implicated in that discrimination and how the resources of political philosophy may nevertheless be employed

in the service of women. Sometimes, feminist political philosophy extends the arguments of traditional political philosophy to indicate that women are unjustly treated and to propose ways in which that injustice might be removed. This is clearest in liberal feminism, where it is argued that since women are essentially the same as men in being rational creatures, they are entitled to the same legal and political rights as men: arguments which defend the rights of man also support the rights of women. Similarly, Marxist and socialist feminism extend the insights of Marxism and socialism in an attempt to expose and remove the oppression of women: Marxist emphasis on the exploitation of labour under capital is supplemented by Marxist feminist emphasis on the exploitation of women under patriarchy.

However, there are also forms of feminist political philosophy which are more critical of traditional political philosophy and which question the very distinctions upon which it is premised. Thus, radical feminist philosophers question the scope of the term 'political' as it is usually used by political philosophers, and argue that by excluding domestic concerns, traditional political philosophy excludes many of the things which are most important to women. The aim here is not to extend the insights of political philosophy, but rather to highlight the ways in which political philosophy itself shows a distinct gender bias.

Yet more radically, the postmodernists have been critical of philosophy's emphasis on truth and objectivity, and some feminists have extended their arguments to suggest that the very language of philosophy, and by extension of political philosophy, is 'man-made'.

Feminist political philosophy is therefore not one thing but many, and feminist political philosophers are deeply divided as to whether traditional political philosophy may be modified so as to include women's interests, or whether it is itself one of the ways in which women's politically disadvantaged position is legitimized and perpetuated.

SUSAN MENDUS

FEUERBACH, LUDWIG ANDREAS (1804–72)

Ludwig Feuerbach, one of the critical Young Hegelian intellectuals of the nineteenth century, has become famous for his radical critique of religious belief. In *Das Wesen des Christentums* (*Essence of Christianity*) (1841) he develops the idea that God does not exist in reality but as a human projection only, and that the Christian principles of love and solidarity should be applied directly to fellow humans rather than being regarded as an indirect reflection of God's love. In religion, the believer 'projects his being into objectivity, and then again makes himself an object of an object, another being than himself'. Religious orientation is an illusion and is unhealthy, as it deprives and alienates the believer from true autonomy, virtue and community, 'for even love, in itself the deepest, truest emotion, becomes by means of religiousness merely ostensible, illusory, since religious love gives itself to man only for God's sake, so that it is given only in appearance to man, but in reality to God' (*Das Wesen des Christentums* 1841). In *Grundsätze der Philosophie der Zukunft* (*Principles of the Philosophy of the Future*) (1843) he extends his criticism to all forms of metaphysics and religion: 'True Dialectics is not the Monologue of the sole Thinker, rather the Dialogue between I and Thou', he writes in paragraph 62 (*Sämmtliche Werke* 1846–66 II: 345), criticizing in particular his former teacher Hegel. The philosophy of the future has to be both sensual and communal, equally based on theory and practice and among individuals. In an anonymous encyclopedia article of 1847 he defines his position: 'the principle from which Feuerbach derives everything and towards which he targets everything is "the human being on the ground and foundation of nature"', a principle which 'bases truth on sensuous experience and thus replaces previous particular and abstract philosophical and religious principles' (*Gesammelte Werke* 1964– III: 331). Feuerbach's sensualism and communalism had great influence on the young Karl Marx's development of an anthropological humanism, and on his contemporaries in providing a cultural and moral system of reference for humanism outside of religious orientation and rationalistic psychology. In the twentieth century, Feuerbach influenced existential theology (Martin Buber, Karl Barth) as well as existentialist and phenomenological thought.

HANS-MARTIN SASS

FEYERABEND, PAUL KARL (1924–94)

Feyerabend was an Austrian philosopher of science who spent most of his academic career in the USA. He was an early, persistent and influential critic of the positivist interpretation of science. Though his views have some affinities with those of Thomas Kuhn, they are in important ways more radical. Not only did Feyerabend become famous (or notorious) for advocating 'epistemological anarchism' – the position that there is no such thing as scientific method, so that in advancing scientific research 'anything goes' – he also argued that the scientific

outlook is itself just one approach to dealing with the world, an approach that is not self-evidently superior in all respects to other approaches. This radicalism led to his being widely attacked as an irrationalist though perhaps he might better be seen as a sceptic in the humane and tolerant tradition of Sextus Empiricus and Montaigne.

MICHAEL WILLIAMS

FICHTE, JOHANN GOTTLIEB (1762–1814)

Fichte developed Kant's Critical philosophy into a system of his own, which he named 'Theory of Science' or *Wissenschaftslehre*. Though Fichte continued to revise this system until the end of his life, almost all of his best-known and most influential philosophical works were written in first portion of his career, when he was a professor at the University of Jena.

The task of philosophy, as understood by Fichte, is to provide a transcendental explanation of ordinary consciousness and of everyday experience, from the standpoint of which philosophy must therefore abstract. Such an explanation can start either with the concept of free subjectivity ('the I') or with that of pure objectivity (the 'thing in itself'), the former being the principle of idealism and the latter that of what Fichte called 'dogmatism' (or transcendental realism). Though neither of these first principles can be theoretically demonstrated, the principle of freedom possesses the advantage of being practically or morally certain. Moreover, according to Fichte, only transcendental idealism, which begins with the principle of subjective freedom and then proceeds to derive objectivity and limitation as conditions for the possibility of any selfhood whatsoever, can actually accomplish the task of philosophy.

One of the distinctive features of Fichte's Jena system is its thoroughgoing integration of theoretical and practical reason, that is, its demonstration that there can be no (theoretical) cognition without (practical) striving, and vice versa. Another important feature is Fichte's demonstration of the necessary finitude of all actual selfhood. The 'absolute I' with which the system seems to begin turns out to be only a practical ideal of total self-determination, an ideal toward which the finite I continuously strives but can never achieve. Also emphasized in Fichte's Jena writings is the social or intersubjective character of all selfhood: an I is an I only in relationship to other finite rational subjects. This insight provides the basis for Fichte's political philosophy or 'theory of right', which is one of the more original portions of the overall system of the *Wissenschaftslehre*, a system that also includes a foundational portion (or 'first philosophy'), a philosophy of nature, an ethics and a philosophy of religion.

DANIEL BREAZEALE

FICINO, MARSILIO (1433–99)

With Giovanni Pico della Mirandola, Marsilio Ficino was the most important philosopher working under the patronage of Lorenzo de'Medici, 'Il Magnifico', in the Florence of the High Renaissance. Ficino's main contribution was as a translator of Platonic philosophy from Greek into Latin: he produced the first complete Latin version of the works of Plato (1484) and Plotinus (1492) as well as renderings of a number of minor Platonists. He supplied many of his translations with philosophical commentaries, and these came to exercise great influence on the interpretation of Platonic philosophy in the Renaissance and early modern periods. Ficino's most important philosophical work, the *Theologia platonica de immortalitate animae* (Platonic Theology, On the Immortality of the Soul) (1474), aimed to use Platonic arguments to combat the Averroists, 'impious' scholastic philosophers who denied that the immortality of the soul could be proven by reason. The most famous concept associated with his name is that of 'Platonic love'.

FICTIONAL ENTITIES

By 'fictional entities', philosophers principally mean those entities originating in and defined by myths, legends, fairy tales, novels, dramas and other works of fiction. In this sense unicorns, centaurs, Pegasus, the Time Machine and Sherlock Holmes are all fictional entities.

A somewhat different category of fictional entities is associated with empiricist philosophy. It includes entities apparently assumed by common discourse but which admit of no direct empirical experience. Thus Jeremy Bentham classified as 'fictitious entities' motion, relation, power and matter, as well as, notoriously, rights, obligations and duties. David Hume called substance, the self, even space and time 'fictions' and Bertrand Russell thought ordinary things, such as Piccadilly or Socrates, were fictions, on the grounds that they

are 'constructed' out of simpler, more immediate objects of acquaintance.

Philosophical interest in fictional entities thus covers a surprisingly wide area of the subject, including ontology and metaphysics, epistemology, logic, philosophy of language, and aesthetics. The first question that arises is how the distinction should be drawn between fictional and nonfictional entities. As the examples from Bentham, Hume and Russell show, this is by no means a straightforward matter. The next question concerns what to do with fictional entities once they have been identified. Here the primary philosophical task has been to try to accommodate two powerful yet apparently conflicting intuitions: on the one hand, the intuition that there are no such things as fictional entities, so that any seeming reference to them must be explained away; on the other hand, the intuition that because 'things' like Sherlock Holmes and Anna Karenina are so vividly drawn, so seemingly 'real', objects of thoughts and emotions, they must after all have some kind of reality. Broadly speaking, we can discern two kinds of philosophical approach: those which incline towards the latter intuition, being in some way hospitable to fictional entities; and the less hospitable kind, which incline towards the former and seek only to show how fictional entities can be eliminated altogether in the strict regime of rational discourse.

FILM, AESTHETICS OF

Film aesthetics has been dominated by issues of realism. Three kinds of realism attributable to film may be distinguished: (1) the realism inherent in film because of its use of the photographic method (realism of method); (2) realism as a style which approximates the normal conditions of perception (realism of style); (3) realism as the capacity of film to engender in the viewer an illusion of the reality and presentness of fictional characters and events (realism of effect). Some theorists have argued that realism of method requires us to avoid realist style, others that it requires us to adopt it. Most have agreed that realist style makes for realism of effect; they disagree about whether this is a desirable goal. It is argued here that these realisms are independent of one another, that realism of style does not entail any kind of metaphysical realism, and that realism of effect is irrelevant to understanding the normal experience of cinema. Realism of style suggests a way of making precise the claim that cinema is an art of time and of space, because this kind of realism is partially explicated in terms of the representation of time by time and of space by space. Psychological theorizing about the cinema has been strongly connected with realism of effect, and with the idea that an illusion of the film's reality is created by the identification of the viewer's position with that of the camera. Another version of illusionism has it that the experience of film-watching is significantly similar to that of dreaming. Such doctrines are undermined when we acknowledge that realism of effect is an insignificant phenomenon.

GREGORY CURRIE

FILMER, SIR ROBERT (1588–1653)

Filmer was one of the most important political thinkers in seventeenth-century England, and the author of *Patriarcha*. Locke replied to this and other works by Filmer in the *Two Treatises of Government* – perhaps the most famous of all works of liberal political theory. Filmer argued that notions of mixed or limited government were false and pernicious, and that the powers of all legitimate rulers were derived not from the people but directly from God, to whom alone rulers were accountable. Filmer's contemporaries commonly held that the authority of a father and husband over his family stemmed not from the consent of his wife and children but from the natural and divinely appointed order of things. Filmer harnessed such ideas to the cause of royal absolutism by arguing that the state and the family were essentially the same institution.

FODOR, JERRY ALAN (1935–)

Jerry Fodor has been one of the most influential figures in the philosophy of mind, the philosophy of psychology, and 'cognitive science' through the latter part of the twentieth century. His primary concern has been to argue (vigorously) for a certain view of the nature of thought. According to this view, thinking is information processing within 'the language of thought'. The mind can be understood

as a computer, which directs action with the aid of internal representations of the world.

PETER GODFREY-SMITH

FOLK PSYCHOLOGY

There is wide disagreement about the meaning of ordinary mental terms (such as 'belief', 'desire', 'pain'). Sellars suggested that our use of these terms is governed by a widely shared theory, 'folk psychology', a suggestion that has gained empirical support in psychological studies of self-attribution and in a growing literature concerning how children acquire (or, in the case of autism, fail to acquire) ordinary mental concepts. Recently, there has been a lively debate about whether people actually 'theorize' about the mind, or, instead, engage in some kind of 'simulation' of mental processes.

FORMALISM IN ART

Formalism in art is the doctrine that the artistic value of a work of art is determined solely by the work's form. The concept of artistic form is multiply ambiguous, however, and the precise meaning of formalism depends upon which sense of form it operates with. There are two main possibilities. The first understands form as the structure of a work's elements, the second as the manner in which it renders its 'content'. If form is understood as structure, formalism is still ambiguous: understood one way, it has never been denied; understood another way, it is untenable. If form is understood as manner, formalism is false.

FORMS, PLATONIC

Plato thought that in addition to the changeable, extended bodies we perceive around us, there are also unchangeable, extensionless entities, not perceptible by the senses, that structure the world and our knowledge of it. He called such an entity a 'Form' (*eidos*) or 'Idea' (*idea*), or referred to it by such phrases as 'the such-and-such itself'. Thus in addition to individual beautiful people and things, there is also the Form of Beauty, or the Beautiful Itself.

It may be speculated that Plato's Presocratic predecessors gave some impetus to this theory. It is a certainty that Socrates was the major influence on it, through his search for the definitions of ethical terms. The features that a definition must have in order to satisfy Socrates' criteria of adequacy foreshadow the features that Forms have in Plato's theory.

Beginning with his *Meno*, Plato turned his attention to the presuppositions of Socrates' investigation, and the preconditions of its possibility: what has to be true about virtue, knowledge and our souls if Socratic cross-examination is to have any hope of success? He answers these questions with a set of doctrines – the existence of Forms, the soul's immortality and its knowledge of Forms through recollection – which are then developed and displayed in the great dialogues of his middle period, the *Phaedo*, *Symposium*, *Phaedrus* and *Republic*. Not all of Plato's thoughts on Forms are on display in the middle-period theory, but this is the theory of Forms that has been far and away the most influential historically, and the one that is most commonly intended when people refer to 'Plato's Forms'.

The dialogues of Plato's later period present a number of puzzles. That his views developed will be agreed by all: in the *Sophist*, *Statesman* and *Philebus* Plato is clearly pushing his metaphysical investigations in new directions. What is less clear is the degree of continuity or rupture between old and new – the *Parmenides* has sometimes been taken to signal Plato's wholesale rejection of the middle-period theory, whereas the *Timaeus* seems to confirm his endorsement of it. Further complicating matters, Aristotle reports that Plato in his last period based the Forms somehow on numbers. The reported material is obscure in itself and also hard to integrate with any of the material from Plato's dialogues.

Much of our current understanding of Plato's middle-period theory comes from a group of arguments that advert to differences between Forms and sensible objects or properties. These arguments tend to support Aristotle's report that the theory arose from a collision between Socrates'

views on definition and Heraclitean views on flux. The general form of the argument claims that definitions, or knowledge, require the existence of a class of entities with certain features, and that sensibles lack those features. It concludes that there exists a class of entities distinct from the familiar sensibles, namely the Forms.

But as often in historical studies, the arguments themselves are silent or ambiguous on many of the points that critics most wish to determine: whether Plato thought Forms exist separately from particulars, whether he treated them as Aristotelian substances, whether it is possible to have knowledge of sensible objects, whether Plato came to reject the middle-period theory, and so on. For the second half of the twentieth century, the tendency was for interpreters to settle the remaining interpretative issues by ascribing to Plato their own philosophical preferences, justifying this by appeal to 'interpretative charity'.

The practice of basing interpretations of Plato's Forms solely on a handful of arguments was a mistake; the increasing tendency to broaden the evidentiary base is a salutary development. Where the interpretation of an argument has left a question unresolved, the consideration of Plato's myths and metaphors may sometimes lend strong weight to one side or the other. An example: Plato's depictions of particulars make it highly implausible that the 'imperfection' in particulars to which some arguments advert is merely the compresence of opposites.

Most of Plato's successors in the early Academy kept up the Forms. Aristotle's writing are full of references to them, and they left visible imprints on his own theory. The Hellenistic period witnessed a blanket rejection of all immaterial entities, but even here the influence of the Forms can still be discerned around the edges. The revival of Platonism at the end of the Hellenistic period saw Forms returned to philosophical respectability.

FOUCAULT, MICHEL (1926–84)

Introduction

Michel Foucault was a French philosopher and historian of thought. Although his earliest writings developed within the frameworks of Marxism and existential phenomenology, he soon moved beyond these influences and developed his own distinctive approaches. There is no overall methodological or theoretical unity to Foucault's thought, but his writings do fall into several main groups, each characterized by distinctive problems and methods. In his early studies of psychiatry, clinical medicine and the social sciences, Foucault developed an 'archaeology of knowledge' that treated systems of thought as 'discursive formations' independent of the beliefs and intentions of individuals. Foucault's archaeology displaced the human subject from the central role it played in the humanism which had been dominant since Kant. While archaeology provided no account of transitions from one system to another, Foucault later introduced a 'genealogical' approach, which seeks to explain changes in systems of discourse by connecting them to changes in the non-discursive practices of social power structures. Like Nietzsche's, Foucault's genealogies refused all comprehensive explanatory schemes, such as those of Marx or Freud. Instead he viewed systems of thought as contingent products of many small, unrelated causes. Foucault's genealogical studies also emphasize the essential connection between knowledge and power. Bodies of knowledge are not autonomous intellectual structures that happen to be employed as Baconian instruments of power. Rather, they are essentially tied to systems of social control. Foucault first used his genealogical approach to study the relations between modern prisons and the psychological and sociological knowledge on which they are based. He next proposed a similar analysis of modern practices and 'sciences' of sexuality, but eventually decided that such a study had to begin with an understanding of ancient Greek and Roman conceptions of the ethical self. The study was published in two volumes that appeared just before his death. Foucault forbade posthumous publication of his writings, but the ban has not included the texts of his public lectures at the Collège de France, several volumes of which have already appeared, with more planned.

1 Biography

Foucault was born on 15 June 1926 in Poitiers, where his father was a prominent physician. In

1946, after preparatory studies with Jean Hyppolite at the Lycée Henri IV, he entered the École Normale Supérieure. He completed advanced degrees in both philosophy and psychology, working with, among others, Maurice Merleau-Ponty. Dissatisfied with French culture and society, Foucault held various academic posts in Sweden, Poland and Germany from 1955 to 1960, while he also completed his thesis (on madness in the Classical Age) for the *doctorat ès lettres*, which he published in 1961. During the 1960s, Foucault held a series of positions in French universities, culminating in 1969 with his election to the Collège de France, where he was Professor of the History of Systems of Thought until he died. Throughout the 1970s and until his death, Foucault was active politically, helping to found the Groupe d'Information sur les Prisions and supporting protests on behalf of homosexuals and other marginalized groups. He also frequently lectured outside France, particularly in the USA, and in 1983 had agreed to teach annually at the University of California at Berkeley. One of the first victims of AIDS, Foucault died in Paris on 25 June 1984.

Contrary to common views of authorship as self-expression, Foucault said that he wrote to escape from himself, to become other than he was. Correspondingly, there is no methodological or theoretical unity of Foucault's thought that will support any single comprehensive interpretation. His writings instead fall into several main groups, each characterized by a distinctive problematic and method of approach. It is fruitful to follow certain themes through some or all of these groups, but the core of his effort at any point is defined by what is specific to the problems then engaging him.

2 The history of madness

Foucault's earliest publications dealt with psychology and mental illness. His initial approach, developed in a long introduction to the French translation of Ludwig Binswanger's *Traum und Existenz* (1954), was through existential phenomenology, particularly that of the early Heidegger. His 1954 book, *Maladie mentale et personnalité* (Mental Illness and Psychology), combined this approach with a Marxist analysis (which, however, Foucault soon decisively rejected). His first major work, *Folie et déraison: histoire de la folie à l'âge classique* (Madness and Civilization) (1961), tried to combine the experiential emphasis of his earlier phenomenological discussions with an essentially historical approach.

Folie et déraison is a challenge to the modern use of the terms 'mad' and 'mentally ill' as synonyms. Beginning in the early nineteenth century, doctors and other therapists rejected such traditional conceptions of madness as divine ecstasy or diabolical possession in favour of the 'enlightened' view that madness is mental illness. Standard histories of psychiatry canonize this view, telling the story of how brave and compassionate men such as Tuke and Pinel replaced superstitious cruelty with scientific treatment of the mad. Foucault's rejection of this view is based on a detailed analysis of the 'experience' of madness that prevailed in the Classical Age (roughly, 1650 to 1800). Then, he maintains, madness was regarded not as mental illness but as a fundamental choice in favour of unreason (*déraison*), where unreason is any basic rejection of the norms of rationality constituting the boundaries of bourgeois social life. Among the various forms of unreason (including sexual promiscuity and deviancy, irreligion and idleness) madness was distinguished by its embracing the animal aspect of human nature at the expense of all higher aspects. The mad were those who had stripped themselves of everything distinctive of their humanity and had chosen to live like beasts. Since, on the classical view, madness was defined by its rejection of reason, the only rational reaction to it was rejection and exclusion. (Foucault regards Descartes' dismissal of his possible madness as grounds for doubt as a paradigm of this point.) Since the Classical Age had no coherent way of giving the mad a place in society, the only alternative was to exclude them from rational society, an exclusion epitomized by the Great Confinement of 1656.

The implication of Foucault's analysis is that there was, even in the relatively recent past of our own culture, a view of madness which was radically different from our own and no less defensible. This alone, he suggests, should begin to undermine our idea that there is something inevitable about our conception of madness. Foucault drives home his point through an analysis of the development of the modern (post-French-Revolution) 'experience' of madness as mental illness. This experience restores a social locus to madness, seeing it as a deviation from norms (an illness), not a rejection of the entire framework of rationality that defines these norms. He takes particular pains to show that, in spite of its veneer of scientific objectivity, the modern view is based more on a moral disapproval of the values implicit in madness than on any objective scientific truth. Similarly, he argues that the modern treatment of the mad (in asylums) was not so much a matter of medical compassion as a concerted effort to bring the mad back beneath the yoke of bourgeois morality. Initiating a theme further developed in various literary essays during the 1960s, *Folie et déraison* continually evokes the lives

and works of artists haunted by madness (Van Gogh, Roussel, Artaud, Nietzsche) as precious expressions of a truth suppressed by both classical and modern experiences of madness.

3 The archaeological method

The second major division of Foucault's work begins with his history of the origins of modern medicine, *Naissance de la clinique: une archéologie du régard médical* (The Birth of the Clinic) (1963). Its first pages suggest that it is an extension of Foucault's ethical critique of the concept of mental illness to that of physical illness. But very soon the study becomes an analysis of the linguistic and conceptual structures underlying the modern practice of medicine; or, in the phrase of its subtitle, 'an archaeology of medical perception'.

Foucault's development of his 'archaeological method' synthesized three fundamental lines of influence on his thought: the history and philosophy of science of Gaston BACHELARD and Georges Canguilhem; the modernist literature of (especially) Raymond Roussel, George Bataille and Maurice Blanchot; and the historiography of Fernand Braudel and his *Annales* School. The point of convergence of these influences was the elimination of the subject as the centre of historical and philosophical analysis. Bachelard and Canguilhem challenged what Foucault called the 'transcendental narcissism' of existential phenomenology through a philosophy of objective concepts opposed to the existentialists' philosophy of subjective experience. Bachelard worked primarily on the physical sciences and Canguilhem on the biological and medical sciences, but Foucault extended their viewpoint to the strongholds of the modern conception of subjectivity: the 'human sciences'. Modernist writing excited Foucault by its potential for, in Bataille's terminology, 'transgressing' the limits of standard knowledge and experience. As illustrated in his essay, 'What Is an Author?' (1969), Foucault was particularly impressed with the modernists' decentring of the author and their constitution of language itself as the essence of literature. Braudel and his school had obtained extremely interesting results by varying the historiographical perspective; that is, by writing history not in terms of individuals' experience but from the broader standpoint of long-term factors such as geography, climate and natural resources. Foucault's archaeology did not take over any of Braudel's specific results or methods but tried to effect a parallel change of perspective in the history of thought: a move away from the individual thinker and towards more fundamental categories and structures.

Foucault's fullest deployment of his archaeological method was in *Les Mots et les choses: une archéologie des sciences humaines* (The Order of Things) (1966), where he analysed the linguistic systems ('epistemes') characteristic of certain periods of thought. In particular, Foucault delineated the linguistic systems underlying the classical disciplines of general grammar, natural history and analysis of wealth, as well as those of the modern disciplines of philosophy, biology and economics that replaced them. He argued that there were strong structural similarities among the three classical disciplines and among the three modern disciplines, but a sharp break between classical and modern modes of thought taken as wholes. On this basis he rejected, for example, the common view that the work of nineteenth-century biologists such as Darwin was a continuous development of the work of eighteenth-century natural historians such as Lamarck. Specifically, he maintained that there is no hint of the Darwinian concept of evolution in Lamarck or any other classical thinker. He took such results as illustrative of the superiority of his archaeological approach to standard history of ideas, which focused on the specific concepts and theories of particular thinkers and not on the linguistic structures underlying them.

L'Archéologie du savoir (The Archaeology of Knowledge) (1969) systematically articulated the methodology Foucault had gradually forged in his preceding historical studies. It did this through an account of discourse, based on his notion of the statement (*l'énoncé*), which described a level of linguistic structure prior to and determining the range of objects, concepts, methodological resources and theoretical formulations available to individuals who speak and write. This account provided a theoretical elucidation of the decentring of the subject effected by Foucault's histories.

4 Genealogy

Foucault's writings during the 1970s constitute a third major division of his work. Although archaeological method is not abandoned in this period, it is subordinated to a new style of analysis that Foucault, with a bow to Nietzsche, dubs 'genealogical'. A genealogical analysis explains changes in systems of discourse by connecting them to changes in the non-discursive practices of social power structures. Foucault recognizes the standard economic, social and political causes of such changes, but he rejects the efforts of many historians to fit these causes into unitary, teleological schemata, such as the rise of the bourgeoisie or Napoleonic ambition. Rather, he sees changes in non-discursive practices as due to a vast number of minute and

unconnected facts, the sorts of 'petty causes' that Nietzsche evoked in his genealogies (see GENEALOGY).

Foucault's genealogical studies emphasize the essential connection between knowledge and power. Bodies of knowledge are not autonomous intellectual structures that happen to be employed as instruments of power. Rather, precisely as bodies of knowledge, they are tied (but not reducible) to systems of social control. This essential connection of power and knowledge reflects Foucault's view that power is not merely repressive but a creative, if always dangerous, source of positive values. Although systems of knowledge may express objective truth in their own right, they are none the less always tied to current regimes of power. Conversely, regimes of power necessarily give rise to bodies of knowledge about the objects they control; but this knowledge may – in its objectivity – go beyond and even ultimately threaten the project of domination from which it arises.

Surveiller et punir: naissance de la prison (Discipline and Punish) (1975) is the best example of Foucault's genealogical approach. Here Foucault applies his conception of knowledge/power to the connection between modern disciplinary practices and modern social scientific disciplines. His primary example is the relation of the practice of imprisonment to such disciplines as criminology and social psychology. But imprisonment quickly becomes a model for the entire range of modern disciplinary practices, as employed in schools, factories, the military and so on. *Discipline and Punish* is a genealogical study in the precise sense that it shows how fundamental changes in thought (the emergence of new social scientific disciplines) were causally connected with changes in non-discursive practices (characteristically modern means of controlling the body).

Foucault's *Histoire de la sexualité* (History of Sexuality) (1976–84) was initially conceived as a straightforward extension of the genealogical approach to sexuality. His idea was that modern bodies of knowledge about sexuality (the 'sciences of sexuality', including psychoanalysis) have an intimate association with the power structures of modern society. Volume 1, published in 1976, was intended as the introduction to a series of studies on particular aspects of modern sexuality (children, women, perverts and population), outlining the basic viewpoint and methods of the project. A central contention was that the history of sexuality is distorted by our acceptance of the 'repressive hypothesis': the proposition that the primary attitude towards sex during the last three centuries was one of opposition, silencing and, as far as possible, elimination. Foucault argues that in fact this period produced a 'discursive explosion' regarding sex, beginning with the rules of the Counter-Reformation governing sacramental confession. These rules emphasized the need for penitents to examine themselves and articulate not just all their sinful sexual actions, but all the thoughts, desires and inclinations behind these actions. The distinctive modern turn is the secularization (in, for example, psychoanalysis) of this concern for knowing and expressing the truth about sex.

Foucault emphasizes the similarities in our views of sex and crime. Both are objects of allegedly scientific disciplines, which simultaneously offer knowledge and domination of their objects. In the case of sexuality, however, control is exercised not only through others' knowledge of individuals but also through individuals' knowledge of themselves. We internalize the norms laid down by the sciences of sexuality and monitor our own conformity to these norms. We are controlled not only as *objects* of disciplines but also as self-scrutinizing and self-forming *subjects*. Foucault thus sees our apparently liberating focus on our sexuality as a reinforcement of the mechanisms of social control. The self-scrutiny that overcomes psychic repression to reveal our deep sexual nature is merely a subtle means of shaping us to the norms of modern society.

5 Sexuality and ethics

Foucault planned the second volume of his history of sexuality as a study of the origins of the modern notion of the subject in the practices of Christian confession. He wrote such a study, 'Les Aveux de la chair' (The Confessions of the Flesh), but did not publish it because he decided that a proper understanding of the Christian development required a comparison with ancient conceptions of the ethical self. This led to two volumes on Greek and Roman sexuality: *L'Usage des plaisirs* (The Use of Pleasure) (1984) and *Le Souci de soi* (The Care of the Self) (1984). These two volumes mark the fourth and final period of Foucault's work, a period most striking for its emphasis on the individual self: the 'problematization' of its world and actions and the 'aesthetics of existence' whereby it makes its life a work of art. It might seem that Foucault has finally rejected the derivative and ephemeral status of the individual. But this would be doubly mistaken. On the one hand, he still sees our history as strongly structured by discursive and non-discursive practices operating at much deeper levels than that of human consciousness. On the other hand, every stage of Foucault's work was directed towards overcoming the limitations of individuals (himself and others). Previously, his effort was the negative one of dissolving the apparently necessary constraints of society and its discourses. In this final turn to what

he calls 'ethics', he began to explore the positive possibilities of self-creation.

In *The Use of Pleasure* and *The Care of the Self*, Foucault compares ancient pagan and Christian ethics through studies of the test case of sexuality. He notes that the moral codes of pagans and Christians were similar, but maintains that there were fundamental differences in the ways in which individuals were subordinated to the codes (in the 'forms of subjectification'). The Greeks of the fourth and fifth centuries BC, unlike the early Christians, did not regard the domain of sexual acts (*ta aphrodisia*) as evil in its own right, but as natural and necessary. The Greeks did see sexual acts as objects of moral concern because of their animality and their great intensity. What was dangerous, however, was not sex in itself but its excesses. Therefore, the Greek mode of subjection to the code of sexual ethics was a matter of the proper use (*chresis*) of pleasures. Unlike the Christians, the Greeks allowed the full range of sexual activities (heterosexual, homosexual, in marriage, out of marriage) within proper moderation. Properly used, sex was a major part of an aesthetics of the self: the self's creation of a beautiful and enjoyable existence.

The Use of Pleasure analyses a variety of primary texts (for instance, those of Plato and Xenophon) in order to understand the classical Greek conception of an aesthetics of existence. *The Care of the Self* continues with studies (of Galen, Artemidorus and Plutarch, for example) showing how later antiquity gradually moved away from this aesthetics towards a hermeneutics of the self. The latter, fully developed only by Christianity, replaced the ideal of aesthetic self-creation with that of a deep understanding of a hidden 'real self'. Foucault regards this Christian conception as the root of our domination by the sciences of sexuality he discussed in *The History of Sexuality I*. Although insisting that there can be no question of 'going back to the Greeks', he suggests that reflection on the aesthetics of existence may help us devise liberating alternatives to the traps of modern sexuality (see SEXUALITY, PHILOSOPHY OF).

Foucault forbade posthumous publication of his writings, but the ban has not included the texts of his public lectures at the Collège de France, several volumes of which have already appeared, with more planned. The volumes published so far include important material on such topics as the hermeneutics of the subject, the concept of the abnormal, psychiatric power and the modern idea of war.

6 Conclusion

It is impossible to understand Foucault's work in the typical manner of histories of philosophy. There is not only no system, but no sustained vision, message or project (which we find even in such mavericks as Nietzsche, Kierkegaard and Wittgenstein). For Foucault, philosophy is always just a means of overcoming some specific set of historical limits. It has no final goal, no specific truth or effect, of its own. It is merely a set of intellectual techniques, tied to a consciousness of the historical enterprise that has been known as philosophy. If philosophy ever transforms its self-conception along the lines of Foucault's practice, then he will be recognized as a great philosopher (or, more likely, as someone who played a major role in eliminating philosophy as it had been understood since Plato). Otherwise, he will in all likelihood remain a minor figure, interesting for his odd historical perspectives and his quirky social criticism.

FOUNDATIONALISM

Some foundationalists are rationalists who rely on intuition and deduction. Others are empiricists, in a broad sense, and accept observation and induction or abduction or yet other ways to support beliefs by means of other beliefs. What they have in common is that they are all willing to hazard a positive view about what in general makes a belief epistemically justified in the way required for it to be a case of knowledge; and they all propose something of the following general form: belief b is justified if and only if either b is foundationally justified through a psychological process of direct apprehension p (such as rational intuition, observation, introspection, and so on) or else b is inferentially justified through a psychological process of reasoning r (such as deduction, induction, abduction, and so on) ultimately from beliefs all of which are acquired or sustained through p. If one rejects all forms of such foundationalism, then a question remains as to what distinguishes in general the cases where a belief is epistemically justified from the cases in which it is not. Can anything general and illuminating be said about what confers epistemic

justification on a belief, and what gives a belief the epistemic status required for it to constitute knowledge (provided it is true)?

ERNEST SOSA

FOURIER, CHARLES (1772–1837)

Fourier was a French utopian socialist who criticized the economic and domestic structures of the modern social world for their failure to respect human nature. He discerned twelve basic human 'passions' which combined to generate 810 basic personality types. On the basis of this account of human diversity, he advocated the establishment of small voluntary communities organized to provide fulfilling work and sexual liberation. Some of the more extravagant elements of his 'social' theory (his views on cosmogony, metempsychosis and 'universal analogy') were played down by his followers.

DAVID LEOPOLD

FRANKFURT SCHOOL

The origins of the circle of philosophers and social scientists now known as the Frankfurt School lie in the 1920s when a number of critics and intellectuals were attempting to adapt Marxism to the theoretical and political needs of the time. The distinguishing feature of the approach adopted by the Frankfurt School lies less in its theoretical orientation than in its explicit intention to include each of the disciplines of the social sciences in the project of a critical theory of society. The objectives of this theoretical innovation vis-à-vis all the traditional Marxist approaches were established by Max Horkheimer in various articles written in the 1920s and 1930s. His critique of neo-idealist philosophy and contemporary empiricism sought to develop a philosophy of history which would comprehend the evolution of human reason; in so doing, he drew on empirical research. Thus the Institute of Social Research, conceived as a way of realizing this plan, was founded in 1929. Its work drew on economics, psychology and cultural theory, seeking to analyse, from a historical perspective, how a rational organization of society might be achieved.

However, after the National Socialists came to power and drove the Institute into exile, historical/philosophical optimism gave way to cultural/critical pessimism. Horkheimer and Adorno now saw it as the function of a critical theory of society to try, by returning to the history of civilization, to establish the reasons for the emergence of Fascism and Stalinism. Their *Dialectic of Enlightenment*, which bears some resemblance to Heidegger, impressively testifies to this change of orientation: it asks why totalitarianism came into being and it identifies a cognitive and practical perspective on the world which, because of its concern with the technical control of objects and persons, only allows for an instrumental rationality.

But there was some opposition to this critique of reason which tended to view totalitarianism as a consequence of an inescapable cycle of instrumental reason and social control. The concept of total reification was called into question by some of the more marginal members of the Institute working under Adorno and Horkheimer. These were far more interested in asking whether, even under totalitarian conditions, they could determine the remains of a desire for communicative solidarity. The work of philosopher Walter Benjamin constitutes an analysis of the interrelation of power and the imagination; Franz Neumann and Otto Kirchheimer inquired into legal consensus culture and social control; while Erich Fromm conducted a psychoanalytic investigation of communicative needs and their potential for resistance.

After the core members of the School had returned from exile, the Institute resumed its work in Frankfurt and embarked on large-scale empirical projects. From the very beginning, however, a considerable gap existed between the empirical investigations which focused on the industrial workplace and the philosophical radicalization of negativity on which Adorno and Horkheimer worked, albeit with differing emphasis. This gap was bridged only when Habermas began to challenge the systematic bases of critical theory, causing the basic philosophical concepts and the intentions of empirical social research once again to correspond. The central idea, with which Habermas introduced a new phase in the history of the Frankfurt School, was his understanding of a form of rationality which would describe the communicative agreement between subjects rather than the instrumental control of things. The concept of communicative rationality which emerged from this idea has since formed the basis for the moral grounds and democratic application of critical theory.

FREE LOGICS

We often need to reason about things that do not – or may not – exist. We might, for example, want to prove that there is no highest prime number by assuming its existence and deriving a contradiction. Our ordinary formal logic, however (that is, anything including standard quantification theory), automatically assumes that every singular term used has a denotation: if you can use the term 'God' – if that term is part of your language – automatically there is a denotation for it, that is, God exists. Some logicians have thought that this assumption prejudges too many important issues, and that it is best to get rid of it. So they have constructed logics free of this assumption, called 'free logics'.

FREE WILL

Introduction

'Free will' is the conventional name of a topic that is best discussed without reference to the will. Its central questions are 'What is it to act (or choose) freely?', and 'What is it to be morally responsible for one's actions (or choices)?' These two questions are closely connected, for freedom of action is necessary for moral responsibility, even if it is not sufficient.

Philosophers give very different answers to these questions, hence also to two more specific questions about ourselves: (1) Are we free agents? and (2) Can we be morally responsible for what we do? Answers to (1) and (2) range from 'Yes, Yes' to 'No, No' – via 'Yes, No' and various degrees of 'Perhaps', 'Possibly', and 'In a sense'. (The fourth pair of outright answers, 'No, Yes', is rare, but appears to be accepted by some Protestants.) Prominent among the 'Yes, Yes' sayers are the *compatibilists*, who hold that free will is compatible with *determinism*. Briefly, determinism is the view that everything that happens is necessitated by what has already gone before, in such a way that nothing can happen otherwise than it does. According to compatibilists, freedom is compatible with determinism because freedom is essentially just a matter of not being constrained or hindered in certain ways when one acts or chooses. Thus normal adult human beings in normal circumstances are able to act and choose freely. No one is holding a gun to their heads. They are not drugged, or in chains, or subject to a psychological compulsion. They are therefore wholly free to choose and act even if their whole physical and psychological make-up is entirely determined by things for which they are in no way ultimately responsible – starting with their genetic inheritance and early upbringing.

Incompatibilists hold that freedom is not compatible with determinism. They point out that if determinism is true, then every one of one's actions was determined to happen as it did before one was born. They hold that one cannot be held to be truly free and finally morally responsible for one's actions in this case. They think compatibilism is a 'wretched subterfuge . . . , a petty word-jugglery', as Kant put it in his *Critique of Practical Reason* (1788). It entirely fails to satisfy our natural convictions about the nature of moral responsibility.

The incompatibilists have a good point, and may be divided into two groups. *Libertarians* answer 'Yes, Yes' to questions (1) and (2). They hold that we are indeed free and fully morally responsible agents, and that determinism must therefore be false. Their great difficulty is to explain why the falsity of determinism is any better than the truth of determinism when it comes to establishing our free agency and moral responsibility. For suppose that not every event is determined, and that some events occur randomly, or as a matter of chance. How can our claim to moral responsibility be improved by the supposition that it is partly a matter of chance or random outcome that we and our actions are as they are?

The second group of incompatibilists is less sanguine. They answer 'No, No' to questions (1) and (2). They agree with the libertarians that the truth of determinism rules out genuine moral responsibility, but argue that the falsity of determinism cannot help. Accordingly, they conclude that we are not genuinely free agents or genuinely morally responsible, whether determinism is true or false. One of their arguments can be summarized as follows. When one acts, one acts in the way one does because of the way one is. So to be truly morally responsible for one's actions, one would have to be truly responsible for the way one is: one would have to be *causa sui*, or the cause of oneself, at least in certain crucial mental respects. But nothing can be *causa sui* – nothing can be the ultimate cause of itself in any respect. So nothing can be truly morally responsible.

Suitably developed, this argument against moral responsibility seems very strong. But in many human beings, the experience of choice gives rise to a conviction of absolute responsibility that is untouched by philosophical arguments. This conviction is the deep and inexhaustible source of the free will problem: powerful arguments that seem to show that we cannot be morally responsible in the ultimate way that we suppose keep coming up against equally powerful psychological reasons why

we continue to believe that we are ultimately morally responsible.

1 Compatibilism

Do we have free will? It depends what you mean by the word 'free'. More than 200 senses of the word have been distinguished; the history of the discussion of free will is rich and remarkable. David Hume called the problem of free will 'the most contentious question of metaphysics, the most contentious science' (*Enquiry Concerning Human Understanding* 1748).

According to *compatibilists*, we do have free will. They propound a sense of the word 'free' according to which free will is compatible with *determinism*, even though determinism is the view that the history of the universe is fixed in such a way that nothing can happen otherwise than it does because everything that happens is necessitated by what has already gone before (see DETERMINISM AND INDETERMINISM).

Suppose tomorrow is a national holiday. You are considering what to do. You can climb a mountain or read Lao Tse. You can mend your bicycle or go to the zoo. At this moment you are reading the *Routledge Encyclopedia of Philosophy.* You are free to go on reading or stop now. You have started on this sentence, but you don't have to . . . finish it.

In this situation, as so often in life, you have a number of options. Nothing forces your hand. It seems natural to say that you are *entirely* free to choose what to do. And, given that nothing hinders you, it seems natural to say that you act entirely freely when you actually do (or try to do) what you have decided to do.

Compatibilists claim that this is the right thing to say. They believe that to have free will, to be a free agent, to be free in choice and action, is simply to be free from *constraints* of certain sorts. Freedom is a matter of not being physically or psychologically forced or compelled to do what one does. Your character, personality, preferences, and general motivational set may be entirely determined by events for which you are in no way responsible (by your genetic inheritance, upbringing, subsequent experience, and so on). But you do not have to be in control of any of these things in order to have compatibilist freedom. They do not constrain or compel you, because compatibilist freedom is just a matter of being able to choose and act in the way one prefers or thinks best *given how one is*. As its name declares, it is compatible with determinism. It is compatible with determinism even though it follows from determinism that every aspect of your character, and everything you will ever do, was already inevitable before you were born.

If determinism does not count as a constraint or compulsion, what does? Compatibilists standardly take it that freedom can be limited by such things as imprisonment, by a gun at one's head, or a threat to the life of one's children, or a psychological obsession and so on.

It is arguable, however, that compatibilist freedom is something one continues to possess undiminished so long as one can choose or act in any way at all. One continues to possess it in any situation in which one is not actually panicked, or literally compelled to do what one does, in such a way that it is not clear that one can still be said to choose or act at all (as when one presses a button, because one's finger is actually forced down on the button).

Consider pilots of hijacked aeroplanes. They usually stay calm. They *choose* to comply with the hijackers' demands. They act responsibly, as we naturally say. They are able to do other than they do, but they choose not to. They do what they most want to do, all things considered, in the circumstances in which they find themselves.

All circumstances limit one's options in some way. It is true that some circumstances limit one's options much more drastically than others; but it does not follow that one is not free to choose in those circumstances. Only literal compulsion, panic, or uncontrollable impulse really removes one's freedom to choose, and to (try to) do what one most wants to do given one's character or personality. Even when one's finger is being forced down on the button, one can still act freely in resisting the pressure, and in many other ways.

Most of us are free to choose throughout our waking lives, according to the compatibilist conception of freedom. We are free to choose between the options that we perceive to be open to us. (Sometimes we would rather not face options, but are unable to avoid awareness of the fact that we do face them.) One has options even when one is in chains, or falling through space. Even if one is completely paralysed, one is still free in so far as one is free to choose to think about one thing rather than another. Sartre observed that there is a sense in which we are 'condemned' to freedom, not free not to be free.

Of course one may well not be able to do everything one wants – one may want to fly

unassisted, vapourize every gun in the United States by an act of thought, or house all those who sleep on the streets of Calcutta by the end of the month. But few have supposed that free will, or free agency, is a matter of being able to do everything one wants. That is one possible view of what it is to be free; but according to the compatibilists, free will is simply a matter of having genuine options and opportunities for action, and being able to choose between them according to what one wants or thinks is best.

It may be said that dogs and other animals can be free agents, according to this basic account of compatibilism. Compatibilists may reply that dogs can indeed be free agents. And yet we do not think that dogs can be free or morally responsible in the way we can be. So compatibilists need to say what the relevant difference is between dogs and ourselves.

Many suppose that it is our capacity for self-conscious thought that makes the crucial difference, because it makes it possible for us to be explicitly aware of ourselves as facing choices and engaging in processes of reasoning about what to do. This is *not* because being self-conscious can somehow liberate one from the facts of determinism: if determinism is true, one is determined to have whatever self-conscious thoughts one has, whatever their complexity. Nevertheless, many are inclined to think that a creature's explicit self-conscious awareness of itself as chooser and agent can constitute it as a free agent in a fundamental way that is unavailable to any unself-conscious agent.

Compatibilists can agree with this. They can acknowledge and incorporate the view that self-conscious awareness of oneself as facing choices can give rise to a kind of freedom that is unavailable to unself-conscious agents. They may add that human beings are sharply marked off from dogs by their capacity to act for reasons that they explicitly take to be moral reasons. In general, compatibilism has many variants. According to Harry Frankfurt's version, for example, one has free will if one wants to be moved to action by the motives that do in fact move one to action. On this view, freedom is a matter of having a personality that is harmonious in a certain way. Freedom in this sense is clearly compatible with determinism.

Compatibilism has been refined in many ways, but this gives an idea of its basis. 'What more could free agency possibly be?', compatibilists like to ask (backed by Hobbes, Locke, and Hume, among others). And this is a very powerful question.

2 Incompatibilism

Those who want to secure the conclusion that we are free agents do well to adopt a compatibilist theory of freedom, for determinism is unfalsifiable, and may be true. (Contemporary physics gives us no more reason to suppose that determinism is false than to suppose that it is true – though this is contested; for further discussion see DETERMINISM AND INDETERMINISM.) Many, however, think that the compatibilist account of things does not even touch the real problem of free will. They believe that all compatibilist theories of freedom are patently inadequate.

What is it, they say, to define freedom in such a way that it is compatible with determinism? It is to define it in such a way that a creature can be a free agent even if all its actions throughout its life are determined to happen as they do by events that have taken place before it is born: so that there is a clear sense in which it could not at any point in its life have done otherwise than it did. This, they say, is certainly not free will. More importantly, it is not a sufficient basis for true moral responsibility. One cannot possibly be truly or ultimately morally responsible for what one does if everything one does is ultimately a deterministic outcome of events that took place before one was born; or (more generally) a deterministic outcome of events for whose occurrence one is in no way ultimately responsible.

These anti-compatibilists or *incompatibilists* divide into two groups: the *libertarians* and the *no-freedom theorists* or *pessimists* about free will and moral responsibility. The libertarians think that the compatibilist account of freedom can be improved on. They hold (1) that we do have free will, (2) that free will is not compatible with determinism, and (3) that determinism is therefore false. But they face an extremely difficult task: they have to show how *indeterminism* (the falsity of determinism) can help with free will and, in particular, with moral responsibility.

The pessimists or no-freedom theorists do not think that this can be shown. They agree with the libertarians that the compatibilist account of free will is inadequate, but they do not think it can be improved on. They agree that free will is not compatible with determinism, but deny that indeterminism can help to make us (or anyone else) free. They believe that free will, of the sort that is necessary for genuine moral responsibility, is provably impossible.

The pessimists about free will grant what everyone must: that there is a clear and important compatibilist sense in which we can be free agents (we can be free, when unconstrained, to choose and to do what we want or think best, given how we are). But they insist that this compatibilist sense of freedom is not enough: it does not give us what we want, in the way of free will; nor does it give us

what we believe we have. And it is not as if the compatibilists have missed something. The truth is that nothing can give us what we (think we) want, or what we ordinarily think we have. All attempts to furnish a stronger notion of free will fail. We cannot be morally responsible, in the absolute, buck-stopping way in which we often unreflectively think we are. We cannot have 'strong' free will of the kind that we would need to have, in order to be morally responsible in this way.

The fundamental motor of the free will debate is the worry about moral responsibility (see RESPONSIBILITY). If no one had this worry, it is doubtful whether the problem of free will would be a famous philosophical problem. The rest of this discussion will therefore be organized around the question of moral responsibility.

First, though, it is worth remarking that the worry about free will does not have to be expressed as a worry about the grounds of moral responsibility. A commitment to belief in free will may be integral to feelings that are extremely important to us independently of the issue of moral responsibility: feelings of gratitude, for example, and perhaps of love. One's belief in strong free will may also be driven simply by the conviction that one is or can be *radically self-determining* in one's actions (in a way that is incompatible with determinism) and this conviction need not involve giving much – or any – thought to the issue of moral responsibility. It seems that a creature could conceive of itself as radically self-determining without having any conception of moral right or wrong at all – and so without being any sort of moral agent.

3 Pessimism

One way of setting out the no-freedom theorists' argument is as follows.

(1) When you act, you do what you do, in the situation in which you find yourself, because of the way you are.

It seems to follow that

(2) To be truly or ultimately morally responsible for what you *do*, you must be truly or ultimately responsible for the way you *are*, at least in certain crucial mental respects. (Obviously you don't have to be responsible for the way you are in all respects. You don't have to be responsible for your height, age, sex, and so on. But it does seem that you have to be responsible for the way you are at least in certain mental respects. After all, it is your overall mental make-up that leads you to do what you do when you act.)

But

(3) You cannot be ultimately responsible for the way you are in any respect at all, so you cannot be ultimately morally responsible for what you do.

Why is it that you cannot be ultimately responsible for the way you are? Because

(4) To be ultimately responsible for the way you are, you would have to have intentionally brought it about that you are the way you are, in a way that is impossible.

The impossibility is shown as follows. Suppose that

(5) You have somehow intentionally brought it about that you are the way you now are, in certain mental respects: suppose that you have intentionally brought it about that you have a certain mental nature N, and that you have brought this about in such a way that you can now be said to be ultimately responsible for having nature N. (The limiting case of this would be the case in which you had simply endorsed your existing mental nature N from a position of power to change it.)

For this to be true

(6) You must already have had a certain mental nature N_{-1}, in the light of which you intentionally brought it about that you now have nature N. (If you did not already have a certain mental nature, then you cannot have had any intentions or preferences, and even if you did change in some way, you cannot be held to be responsible for the way you now are.)

But then

(7) For it to be true that you and you alone are truly responsible for how you now are, you must be truly responsible for having had the nature N_{-1} in the light of which you intentionally brought it about that you now have nature N.

So

(8) You must have intentionally brought it about that you had that nature N_{-1}. But in that case, you must have existed already with a prior nature, N_{-2}, in the light of which you intentionally brought it about that you had the nature N_{-1}.

And so on. Here one is setting off on a potentially infinite regress. In order for one to be truly or ultimately responsible for *how one is*, in such a way

that one can be truly morally responsible for *what one does*, something impossible has to be true: there has to be, and cannot be, a starting point in the series of acts of bringing it about that one has a certain nature – a starting point that constitutes an act of ultimate self-origination.

There is a more concise way of putting the point: in order to be truly morally responsible for what one does, it seems that one would have to be the ultimate cause or origin of oneself, or at least of some crucial part of one's mental nature. One would have to be *causa sui*, in the old terminology. But nothing can be truly or ultimately *causa sui* in any respect at all. Even if the property of being *causa sui* is allowed to belong (unintelligibly) to God, it cannot plausibly be supposed to be possessed by ordinary finite human beings. 'The *causa sui* is the best self-contradiction that has been conceived so far', as Nietzsche remarked in *Beyond Good and Evil*:

> it is a sort of rape and perversion of logic. But the extravagant pride of man has managed to entangle itself profoundly and frightfully with just this nonsense. The desire for 'freedom of the will' in the superlative metaphysical sense, which still holds sway, unfortunately, in the minds of the half-educated; the desire to bear the entire and ultimate responsibility for one's actions oneself, and to absolve God, the world, ancestors, chance, and society involves nothing less than to be precisely this *causa sui* and, with more than Baron Münchhausen's audacity, to pull oneself up into existence by the hair, out of the swamps of nothingness.
> (1886: §21)

In fact, nearly all of those who believe in strong free will do so without any conscious thought that it requires ultimate self-origination. Nevertheless, this is the only thing that could actually ground the kind of strong free will that is regularly believed in, and it does seem that one way in which the belief in strong free will manifests itself is in the very vague and (necessarily) unexamined belief that many have that they are somehow or other radically responsible for their general mental nature, or at least for certain crucial aspects of it.

The pessimists' argument may seem contrived, but essentially the same argument can be given in a more natural form as follows. (i) It is undeniable that one is the way one is, initially, as a result of heredity and early experience. (ii) It is undeniable that these are things for which one cannot be held to be in any way responsible (this might not be true if there were reincarnation, but reincarnation would just shift the problem backwards). (iii) One cannot at any later stage of one's life hope to accede to true or ultimate responsibility for the way one is by trying to change the way one already is as a result of one's heredity and previous experience. For one may well try to change oneself, but (iv) both the particular way in which one is moved to try to change oneself, and the degree of success in one's attempt at change, will be determined by how one already is as a result of heredity and previous experience. And (v) any further changes that one can bring about only after one has brought about certain initial changes will in turn be determined, via the initial changes, by heredity and previous experience. (vi) This may not be the whole story, for it may be that some changes in the way one is are traceable to the influence of indeterministic or random factors. But (vii) it is foolish to suppose that indeterministic or random factors, for which one is *ex hypothesi* in no way responsible, can in themselves contribute to one's being truly or ultimately responsible for how one is.

The claim, then, is not that people cannot change the way they are. They can, in certain respects (which tend to be exaggerated by North Americans and underestimated, perhaps, by members of many other cultures). The claim is only that people cannot be supposed to change themselves in such a way as to be or become truly or ultimately responsible for the way they are, and hence for their actions. One can make the point by saying that the way you are is, ultimately, in every last detail, a matter of luck – good or bad.

4 Moral responsibility

Two main questions are raised by the pessimists' arguments. First, is it really true that one needs to be self-creating or *causa sui* in some way, in order to be truly or ultimately responsible for what one does, as step (2) of the pessimists' argument asserts? Addressing this question will be delayed here until §6, because a more basic question arises: What notion of responsibility is being appealed to in this argument? What exactly is this 'ultimate' responsibility that we are held to believe in, in spite of Nietzsche's scorn? And if we do believe in it, what makes us believe in it?

One dramatic way to characterize the notion of ultimate responsibility is by reference to the story of heaven and hell: 'ultimate' moral responsibility is responsibility of such a kind that, if we have it, it *makes sense* to propose that it could be just to punish some of us with torment in hell and reward others with bliss in heaven. It makes sense because what we do is absolutely up to us. The words 'makes sense' are stressed because one certainly does not have to believe in the story of heaven and hell in order to understand the notion of ultimate responsibility that it is used to illustrate. Nor does one have to believe

in the story of heaven and hell in order to believe in ultimate responsibility (many atheists have believed in it). One does not have to have heard of it.

The story is useful because it illustrates the *kind* of absolute or ultimate responsibility that many have supposed – and do suppose – themselves to have. It becomes particularly vivid when one is specifically concerned with moral responsibility, and with questions of desert; but it serves equally well to illustrate the sense of radical freedom and responsibility that may be had by a self-conscious agent that has no concept of morality. And one does not have to refer to the story of heaven and hell in order to describe the sorts of everyday situation that seem to be primarily influential in giving rise to our belief in ultimate responsibility. Suppose you set off for a shop on the eve of a national holiday, intending to buy a cake with your last ten pound note. Everything is closing down. There is one cake left; it costs ten pounds. On the steps of the shop someone is shaking an Oxfam tin. You stop, and it seems completely clear to you that it is entirely up to you what you do next. That is, it seems clear to you that you are truly, radically free to choose, in such a way that you will be ultimately responsible for whatever you do choose. You can put the money in the tin, or go in and buy the cake, or just walk away. (You are not only completely free to choose. You are free not to choose.)

Standing there, you may believe that determinism is true. You may believe that in five minutes' time you will be able to look back on the situation and say, of what you will by then have done, 'It was determined that I should do that'. But even if you do believe this, it does not seem to undermine your current sense of the absoluteness of your freedom, and of your moral responsibility for your choice.

One diagnosis of this phenomenon is that one cannot really believe that determinism is true, in such situations of choice, and cannot help thinking that the falsity of determinism might make freedom possible. But the feeling of ultimate responsibility seems to remain inescapable even if one does not think this, and even if one has been convinced by the entirely general argument against ultimate responsibility given in §3. Suppose one accepts that no one can be in any way *causa sui*, and yet that one would have to be *causa sui* (in certain crucial mental respects) in order to be ultimately responsible for one's actions. This does not seem to have any impact on one's sense of one's radical freedom and responsibility, as one stands there, wondering what to do. One's radical responsibility seems to stem simply from the fact that one is fully conscious of one's situation, and knows that one can choose, and believes that one action is morally better than the other. This seems to be immediately enough to confer full and ultimate responsibility. And yet it cannot really do so, according to the pessimists. For whatever one actually does, one will do what one does because of the way one is, and the way one is is something for which one neither is nor can be responsible, however self-consciously aware of one's situation one is.

The example of the cake may be artificial, but similar situations of choice occur regularly in human life. They are the experiential rock on which the belief in ultimate responsibility is founded. The belief often takes the form of belief in specifically moral, desert-implying responsibility. But, as noted, an agent could have a sense of ultimate responsibility without possessing any conception of morality, and there is an interesting intermediate case: an agent could have an irrepressible experience of ultimate responsibility, and believe in objective moral right and wrong, while still denying the coherence of the notion of desert.

5 Metaphysics and moral psychology

We now have the main elements of the problem of free will. It is natural to start with the compatibilist position; but this has only to be stated to trigger the objection that compatibilism cannot possibly satisfy our intuitions about moral responsibility. According to this objection, an incompatibilist notion of free will is essential in order to make sense of the idea that we are genuinely morally responsible. But this view, too, has only to be stated to trigger the pessimists' objection that indeterministic occurrences cannot possibly contribute to moral responsibility: one can hardly be supposed to be more truly morally responsible for one's choices and actions or character if indeterministic occurrences have played a part in their causation than if they have not played such a part. Indeterminism gives rise to unpredictability, not responsibility. It cannot help in any way at all.

The pessimists therefore conclude that strong free will is not possible, and that ultimate responsibility is not possible either. So no punishment or reward is ever truly just or fair, when it comes to moral matters.

This conclusion may prompt a further question: What exactly is this 'ultimate' responsibility that we are supposed to believe in? One answer refers to the story of heaven and hell, which serves to illustrate the *kind* of responsibility that is shown to be impossible by the pessimists' argument, and which many people do undoubtedly believe themselves to have, however fuzzily they think about the matter. A less colourful answer has the same import, although it needs more thought: 'ultimate' responsibility exists if and only if punishment and reward can be fair without having any pragmatic justification.

Now the argument may cycle back to compatibilism. Pointing out that 'ultimate' moral responsibility is obviously impossible, compatibilists may claim that we should rest content with the compatibilist account of things – since it is the best we can do. But this claim reactivates the incompatibilist objection, and the cycle continues.

There is an alternative strategy at this point: quit the traditional metaphysical circle for the domain of *moral psychology*. The principal positions in the traditional metaphysical debate are clear. No radically new option is likely to emerge after millennia of debate. The interesting questions that remain are primarily psychological: Why do we believe we have strong free will and ultimate responsibility of the kind that can be characterized by reference to the story of heaven and hell? What is it like to live with this belief? What are its varieties? How might we be changed by dwelling intensely on the view that ultimate responsibility is impossible?

A full answer to these questions is beyond the scope of this entry, but one fundamental cause of our belief in ultimate responsibility has been mentioned. It lies in the experience of choice that we have as self-conscious agents who are able to be fully conscious of what they are doing when they deliberate about what to do and make choices. (We choose between the Oxfam box and the cake; or we make a difficult, morally neutral choice about which of two paintings to buy.) This raises an interesting question: Is it true that any possible self-conscious creature that faces choices and is fully aware of the fact that it does so must experience itself as having strong free will, or as being radically self-determining, simply in virtue of the fact that it is a self-conscious agent (and whether or not it has a conception of moral responsibility)? It seems that we cannot live or experience our choices as determined, even if determinism is true. But perhaps this is a human peculiarity, not an inescapable feature of any possible self-conscious agent. And perhaps it is not even universal among human beings.

Other causes of the belief in strong free will have been suggested. Hume stressed our experience of serious indecision, as above. Spinoza proposed that one of the causes is simply that we are not conscious of the determined nature of our desires. Kant held that our experience of moral obligation makes belief in strong free will inevitable. P.F. Strawson argued that the fundamental fact is that we are irresistibly committed to certain natural reactions to other people, like gratitude and resentment. Various other suggestions have been made: those who think hard about free will are likely to become convinced that investigation of the complex moral psychology of the belief in freedom, and of the possible moral and psychological consequences of altering the belief, is the most fruitful area of research that remains. New generations, however, will doubtless continue to launch themselves onto the old metaphysical roundabout.

6 Challenges to pessimism

The preceding discussion attempts to illustrate the internal dynamic of the free will debate, and to explain why the debate is likely to continue for as long as human beings can think. The basic point is this: powerful logical or metaphysical reasons for supposing that we cannot have strong free will keep coming up against equally powerful psychological reasons why we cannot help believing that we do have it. The pessimists' or no-freedom theorists' conclusions may seem irresistible during philosophical discussion, but they are likely to lose their force, and seem obviously irrelevant to life, when one stops philosophizing.

Various challenges to the pessimists' argument have been proposed, some of which appear to be supported by the experience or 'phenomenology' of choice. One challenge grants that one cannot be ultimately responsible for one's mental nature – one's character, personality, or motivational structure – but denies that it follows that one cannot be truly morally responsible for what one does (it therefore challenges step (2) of the argument set out in §3).

This challenge has at least two versions. One has already been noted: we are attracted by the idea that our capacity for fully explicit self-conscious deliberation, in a situation of choice, suffices by itself to constitute us as truly morally responsible agents in the strongest possible sense. The idea is that such full self-conscious awareness somehow renders irrelevant the fact that one neither is nor can be ultimately responsible for any aspect of one's mental nature. On this view, the mere fact of one's self-conscious presence in the situation of choice can confer true moral responsibility: it may be undeniable that one is, in the final analysis, wholly constituted as the sort of person one is by factors for which one cannot be in any way ultimately responsible; but the threat that this fact appears to pose to one's claim to true moral responsibility is simply obliterated by one's self-conscious awareness of one's situation.

The pessimists reply: This may correctly describe a strong source of *belief* in ultimate (moral) responsibility, but it is not an account of something that could *constitute* ultimate (moral) responsibility. When one acts after explicit self-conscious deliberation, one acts for certain reasons. But which reasons finally weigh with one is a matter of one's mental nature, which is something for which one cannot be in any way ultimately responsible. One can certainly be a morally responsible agent in the sense of being

aware of distinctively moral considerations when one acts. But one cannot be morally responsible in such a way that one is ultimately deserving of punishment or reward for what one does.

The conviction that fully explicit self-conscious awareness of one's situation can be a sufficient foundation of strong free will is extremely powerful. The no-freedom theorists' argument seems to show that it is wrong, but it is a conviction that runs deeper than rational argument, and it survives untouched, in the everyday conduct of life, even after the validity of the no-freedom theorists' argument has been admitted.

Another version of the challenge runs as follows. The reason why one can be truly or ultimately (morally) responsible for what one does is that one's *self* – what one might call the 'agent self' – is, in some crucial sense, independent of one's general *mental nature* (one's character, personality, motivational structure, and so on). One's mental nature *inclines* one to do one thing rather than another, but it does not thereby *necessitate* one to do one thing rather than the other. (The distinction between inclining and necessitating derives from Leibniz (*Discourse on Metaphysics* 1686; *New Essays on Human Understanding* 1704–5).) As an agent-self, one incorporates a power of free decision that is independent of all the particularities of one's mental nature in such a way that one can, after all, count as truly and ultimately morally responsible in one's decisions and actions even though one is not ultimately responsible for any aspect of one's mental nature.

The pessimists reply: Even if one grants the validity of this conception of the agent-self for the sake of argument, it cannot help to establish ultimate moral responsibility. According to the conception, the agent-self decides in the light of the agent's mental nature but is not determined by the agent's mental nature. The following question immediately arises: *Why* does the agent-self decide as it does? The general answer is clear. Whatever the agent-self decides, it decides as it does because of the overall way it is; and this necessary truth returns us to where we started. For once again, it seems that the agent-self must be responsible for being the way it is, in order to be a source of true or ultimate responsibility. But this is impossible, for the reasons given in §3: nothing can be *causa sui* in the required way. Whatever the nature of the agent-self, it is ultimately a matter of luck (or, for those who believe in God, a matter of grace). It may be proposed that the agent-self decides as it does partly or wholly because of the presence of indeterministic occurrences in the decision process. But it is clear that indeterministic occurrences can never be a source of true (moral) responsibility.

Some believe that free will and moral responsibility are above all a matter of being governed in one's choices and actions by reason – or by Reason with a capital 'R'. But possession of the property of being governed by Reason cannot be a ground of radical moral responsibility as ordinarily understood. It cannot be a property that makes punishment (for example) ultimately just or fair for those who possess it, and unfair for those who do not possess it. Why not? Because to be morally responsible, on this view, is simply to possess one sort of motivational set among others. It is to value or respond naturally to rational considerations – which are often thought to include moral considerations by those who propound this view. It is to have a general motivational set that may be attractive, and that may be more socially beneficial than many others. But there is no escape from the fact that someone who does possess such a motivational set is simply lucky to possess it – if it is indeed a good thing – while someone who lacks it is unlucky.

This may be denied. It may be said that some people struggle to become more morally responsible, and make an enormous effort. Their moral responsibility is then not a matter of luck; it is their own hard-won achievement.

The pessimists' reply is immediate. Suppose you are someone who struggles to be morally responsible, and make an enormous effort. Well, that, too, is a matter of luck. You are lucky to be someone who has a character of a sort that disposes you to make that sort of effort. Someone who lacks a character of that sort is merely unlucky. Kant is a famous example of a philosopher who was attracted by the idea that to display free will is to be governed by Reason in one's actions. But he became aware of the problem just described, and insisted, in a later work (*Religion in the Limits of Reason Alone* 1793), that 'man *himself* must make or have made himself into whatever, in a moral sense, whether good or evil, he is to become. Either condition must be an effect of his free choice; for otherwise he could not be held responsible for it and could therefore be *morally* neither good nor evil'. Since he was committed to belief in ultimate moral responsibility, Kant held that such self-creation does indeed take place, and wrote accordingly of 'man's character, which he himself creates' (*Critique* 1788), and of 'knowledge [that one has] of oneself as a person who… is his own originator' (*Opus Postumum* 1993). Here he made the demand for self-creation that is natural for someone who believes in ultimate moral responsibility and who thinks through what is required for it.

In the end, luck swallows everything. This is one way of putting the point that there can be no ultimate responsibility, given the natural, strong

conception of responsibility that was characterized at the beginning of §4. Relative to that conception, no punishment or reward is ever ultimately just or fair, however natural or useful or otherwise humanly appropriate it may be or seem.

The facts are clear, and they have been known for a long time. When it comes to the metaphysics of free will, André Gide's remark is apt: 'Everything has been said before, but since nobody listens we have to keep going back and beginning all over again.' It seems that the only freedom that we can have is compatibilist freedom. If – since – that is not enough for ultimate responsibility, we cannot have ultimate responsibility. The only alternative to this conclusion is to appeal to God and mystery – this in order to back up the claim that something that appears to be provably impossible is not only possible but actual.

The debate continues; some have thought that philosophy ought to move on. There is little reason to expect that it will do so, as each new generation arises bearing philosophers gripped by the conviction that they can have ultimate responsibility. Would it be a good thing if philosophy did move on, or if we became more clear-headed about the topic of free will than we are? It is hard to say.

FREEDOM AND LIBERTY

Introduction

There are at least two basic ideas in the conceptual complex we call 'freedom'; namely, rightful self-government (autonomy), and the overall ability to do, choose or achieve things, which can be called 'optionality' and defined as the possession of open options. To be autonomous is to be free in the sense of 'self-governing' and 'independent', in a manner analogous to that in which sovereign nation states are free. Optionality is when a person has an open option in respect to some possible action, *x*, when nothing in the objective circumstances prevents them from doing *x* should they choose to do so, and nothing requires them to do *x* should they choose not to. One has freedom of action when one can do what one wills, but in order to have the full benefit of optionality, it must be supplemented by freedom of choice (free will), which consists in being able to will what one wants to will, free of internal psychological impediments. Autonomy and optionality can vary independently of one another. A great deal of one can coexist with very little of the other.

Perhaps the most controversial philosophical question about the analysis of freedom concerns its relation to wants or desires. Some philosophers maintain that only the actual wants that a person has at a given time are relevant to their freedom, and that a person is free to the extent that they can do what they want, even if they can do very little else. Other philosophers, urging that the function of freedom is to provide 'breathing space', insist that freedom is a function of a person's ability to satisfy possible (hypothetical) as well as actual wants. A third group consists of those who hold a 'value-oriented' theory according to which freedom is not merely the power of doing what one wants or may come to want, rather it is the capacity of doing something 'worth doing or enjoying', something that is important or significant to the person said to be free, or to others.

1 Freedom and liberty

These two terms are often used interchangeably, but on those occasions when they are not taken to be synonyms, the basis of the distinction between the two is usually clear. 'Freedom', when applied to persons and their actions, refers to the *ability* of a person in a given set of circumstances to act in some particular way. 'Liberty' refers to authoritative *permission* to act in some particular way. The contrast is a basis for the grammatical distinction between 'can' and 'may', between the *de facto* and the *de jure* perspectives, or between (overall) ability and permission.

The concept of a liberty is an important part of juridical systems. A set of governing rules can impose *duties* on those who are subject to their authority. But when the rules remain silent about a given type of activity, *x*, then they are said to leave the subjects *at liberty* to *x* or not to *x*, or however they see fit. To be at liberty to *x* is simply to have no duty not to *x* (see RIGHTS §2).

So conceived, freedom and liberty can vary independently. For example, when a statute is only sporadically enforced, if at all, it may leave a person's *de facto* ability to do what it prohibits virtually unimpaired. Thus a cohabiting unmarried couple in Arizona is perfectly capable of doing what the law prohibits only because the law in question is hardly ever enforced. Cohabiting couples have almost perfect *de facto* freedom to cohabit because police indifference makes the risk of detection and conviction minimal. Not only are we sometimes free (to some degree or other) to do what we are not at liberty to do; conversely, we may be at liberty to do what we are not free to do, as when circumstances other than enforced rules prevent us from doing what we are legally permitted to do.

2 Freedom as autonomy

Judgments of freedom are made not only about individual persons but also about their political communities. Many nation states at some point in their histories have had occasion to declare their independence or, what amounts to the same thing, their sovereignty or status as free states. At the same time, other countries may have lost their freedom (independence) and become mere colonies of stronger nation states. When a political state becomes unfree in this way, each citizen can think of themselves as also deprived of the same kind of freedom, or something analogous to it, for few of them remain entirely self-governed when their own country is governed from afar by masters who simply impose their directives by force. 'None of us are truly free so long as our nation is not', a local patriot might say, even while conceding that the colonial power that governs them has treated them decently, allowing them many freedoms. The question of who rightly governs them, as Sir Isaiah Berlin puts it, is logically distinct from the question of how their governors – foreign or domestic, legitimate or not – protect their liberties. The first question concerns autonomy; the second concerns optionality.

Autonomy and optionality also can vary independently. National autonomy can produce its own tyranny, as when a newly independent nation, free of its colonial repressors, refuses to govern democratically and recognizes no civil rights among its subjects. In such a case the native populace may feel as badly mistreated, if not worse, by their own government as before by the colonizers.

Autonomy or self-government can consist of sharing with one's fellow citizens political independence, or can consist of self-direction by that element of the self authorized by nature to rule (often identified with reason). To be self-governed requires that we not be governed by illegitimate outsiders and equally not by alien forces from within.

Note the close analogy to slavery. One slave owner, *A*, is very severe with his only slave, *S1*, permitting him only minimal free movement, no choice in deciding what his off-duty conduct shall be, or what he shall read, how he dresses and so on. Another slave-owner, *B*, is very easy-going. He treats his only slave, *S2*, as if he were a valued friend, and allows him to do anything short of harming others or leaving the plantation. It is clearly understood that *S2* may do all these things only because *B* permits him to, not as a matter of right. The only rights in this situation are *B*'s property rights. The rules of property ownership permit *B* to be as tough with *S2* as he wishes, but he prefers to be kind. So there is in *S2*'s situation a predominance of heteronomy (government by others) conjoined with high optionality (*de facto* freedom). It seems clear then that one can have little or no autonomy, and yet live a contented life with a high standard of living, something resembling friendship and respect, and most important – options left open for one's own choice to exercise, though not as a matter of right.

Suppose that in respect to a certain choice there are two possibilities left open for *S2*. His master can restore his autonomy and turn him loose into an unfriendly world where other human beings, even though they lack authority over him, treat him badly, effectively closing many key options that would have been left open for him by his earlier beneficent master. Should he accept this offer at the expense of much *de facto* freedom? If the question is a difficult one, it shows that it is not clear to which of the two contending values, independence or optionality, he attaches the greater importance (see AUTONOMY, ETHICAL).

3 Negative and positive freedom

Philosophical advocates of 'positive freedom' are often reacting to a tradition among English empiricists that extends from HOBBES to J.S. MILL and RUSSELL. Hobbes intended his definition to apply to the most essential of the common elements in free action and free movement generally. He defined 'free' as the absence of

external impediments, to apply equally well, for example, to free-flowing (undammed) streams of water as to the purposeful conduct of human beings. Subsequent empiricists, including Locke (§10) and Hume (§5), also held that all freedom is essentially something negative; namely, the absence of restraint or impediment to our actions.

The family of theories to which Berlin attached the label 'positive liberty' are those that identify freedom (or liberty) with personal autonomy or self-government. One version of that theory emphasizes the internal forum that is the agent's self and the legitimate claim of the rational self to rule over the self's lesser elements. The second of the autonomy theories is less individualistic and more political. It holds that no individual can live their life autonomously except as a member of a free political community, a state that is not only independent of other states, but one that is itself organized democratically so that all citizens can share in its governance, and in that sense, at least, be self-governing.

The nineteenth-century idealist philosopher T.H. Green summed up these requirements in his definition of 'freedom' as a 'positive power or capacity of doing or enjoying something worth doing or enjoying, and that too, something that we do or enjoy in common with others' ('Liberal Legislation and Freedom of Contract' 1888). Green's definition also expresses a second conception of positive freedom as more than the mere absence of impediment to our desires, even more than the absence of impediment to our 'worthy' desires. In addition to the absence of constraint, genuine freedom must provide full opportunity beyond the mere non-interference of the police and other people. If a person desires above all things to own and enjoy a Mercedes, and there are no external impediments, legal or nonlegal, in the community to such ownership, then both the legal code and the neighbours leave them free to do as they desire. But if that person has no money, then that negative freedom is effectively useless. To have true freedom, say supporters of positive freedom, one must have what is required for the satisfaction of worthwhile wants, and that will usually include at least minimal wealth, physical health, talent and knowledge, including the sorts of knowledge normally imparted by formal education. The more we are able to do the things worth doing, they insist, the freer we are.

The positive freedom theorists may go on to charge that the negative theorist cannot explain why the laudatory title of freedom should ever characterize the person who is paralysed, insane, infantile, impoverished and ignorant, as generally free. It must be ironic, they claim, to say that such an unfortunate person is well off in the manner implied by the term 'free'. Negative freedom theorists argue that to be free does not mean to be well off; one may be free but discontented, unhappy, ignorant, hungry or in pain. An individual may have freedom but find that in their circumstances it is not worth much. What this shows is that freedom is the kind of good whose worth fluctuates, or in the words of John Rawls (§§1–2): 'the worth of liberty is not the same for everyone' (*A Theory of Justice* 1971: 204).

The pauper is *unable* to buy the Mercedes, but according to the negative freedom advocate, this is not through being *unfree* to buy one. Most writers within the negative freedom tradition deny that all inabilities are also 'unfreedoms'. The inabilities that constitute unfreedoms, they insist, are those that can be traced directly or indirectly to the deliberate actions or policies of other human beings, in particular legislators and police offers, who can intervene directly and forcefully in other persons' lives. Sometimes the relevant explanation of some other person's incapacity (for example, to earn a decent living) can be linked indirectly to various social influences. The impoverished person might be so because of a lack of technical skill, and that lack, in turn, could be a product of a poor education traceable, however obscurely, to the inequities of a national system of racial segregation, which in turn was supported as deliberate policy by an apartheid government. In that case we could say not only that they are unable to do *x*, but also that they are unfree, given the circumstances, to do so.

The gap between the positive and negative theorists can be further decreased by a theory which has a wider conception of 'restraint' and 'impediment.' Such a theory would have a place both for negative constraints like lack of money, and internal constraints like intense headaches. Such a theory could support negative freedom (that all freedom consists of the absence of impediments, whether positive, negative, internal or external), yet also encompass the important point made by positive freedom (that there is a lot more to freedom than simple non-interference from police officers and other persons, important as that is).

A large number of philosophers now reject the view that there are two irreducibly distinct concepts of freedom, one positive and the other negative. These 'single concept' theorists do not contend that one of the pair of allegedly distinct concepts is 'the only, the "truest", or the "most worthwhile"' (MacCallum, 'Negative and Positive Freedom' 1967: 312), but rather that it is a mistake to make the distinction between positive and negative concepts in the first place. According to MacCallum, there is only one concept of liberty and that is

best understood as 'always one and the same triadic relation' between a person (subject or agent), an intended action (actual or possible) and what MacCallum calls a 'preventing condition' (barriers, compulsions and constraints) ('Negative and Positive Freedom': 312, 314). Freedom, in his view, is always *of* someone, *from* something, *to* do, have or be something. Disputes about the nature of freedom like that which divided adherents of positive freedom from adherents of negative freedom are, according to MacCallum, really disagreements over the proper range of one or more of the three variables in a single analytic model: what the term 'person' is to stand for, what is to count as an obstacle, or impediment, or forceful interference, and what is to count as a wanted or intended action.

4 Freedom as optionality

Among the controversies that still divide writers about freedom is the question of whether freedom (in the sense of optionality alone) should be conceived of as simply the absence of present frustration or whether it is best understood as the absence of wider opportunities to do more than one wants to do now. We can call the former concept the 'actual-want satisfaction' theory and the latter the 'hypothetical-want' or 'dispositional' theory. The former allows a person to be called free to the extent that they can satisfy their present wants, without hindrance or frustration. The dispositional concept, however, will not consider them free unless they can also do things that they do not want to do at that present moment, but could, for all they now know, come to want to do at some future time. Why, one might ask, would added dispositional freedom be of value to the person whose actual wants are always permitted their satisfaction? Why should a person miss merely hypothetical want-satisfaction when they can do everything they want without frustration? The usual answer to this question points out that the love of freedom can be a love of breathing space, or room to manoeuvre, of frequent opportunities to change one's mind. The hypothetical account of optionality, therefore, can also be called the 'breathing space' theory.

The most influential spokesmen for the 'actual-wants' concept were the ancient Stoics (see Stoicism). According to Stoic teaching, there are two ways a person can increase the degree of their want-satisfaction. One is to leave their wants as they are and work for the means to satisfy them. The second is to avoid trying to change the world – that is the path to misery – but instead to develop the techniques for changing desires so that they always accord with what happens. The Stoic does not need any breathing space. Whatever happens will please them because their only desire is that God's will be done, and since Zeus is believed to be omnipotent, that desire cannot be frustrated.

Consider Dorothy Doe, who can choose among 1,000 things at time *t*, but is prevented from choosing, or actually doing, the one thing she wants most to do. Richard Roe, on the other hand, can only do one thing at time *t*, but it happens to be the one thing he wants most to do. Richard Roe, one should say, is not simply 'comparatively' or 'largely' unfree; rather, he is totally unfree, for to say that he can do only one thing is to say that he is forced or made to do that thing. And it is beyond controversy that one cannot be both free and compelled to do the same thing. It may be the case, however, that Richard Roe will be entirely content with the arrangement, and actually welcome the compulsion, which if so, shows again that one can sometimes find more contentment in being unfree than in being free. This at least is the message derived from the example by the hypothetical-wants theorist. The actual-wants theorist will deny that Roe is truly unfree; after all, Roe *can* do what he most wants to do.

Dorothy Doe, on the other hand, may have just lost her last chance to pursue a career as a medical researcher, or her last chance to marry the man she loves, or to find a cure for her child's disease. But she does 'enjoy' thousands more options than Richard Roe. She might seem to be freer in respect (say) to prospective marriage partners (one hundred philosophers are eager to marry her tomorrow, but she loathes them all). But her greater freedom is of no significant use. She will be unhappier but more free than Roe. This example may please the breathing space theorist more than the actual-wants theorist, but it may give still more support to the value-oriented philosopher of freedom considered next.

Is Dorothy Doe really more free simply by having more open options? Does not the superior desirability, in her judgment, of some of the options count as well as the sheer number of them? The proponent of the hypothetical-wants theory of freedom often baulks at permitting desirability into our determinations, partly because of the danger that philosophers will reduce the issue to a purely normative question to be settled by considering which definition of the word 'free' links its meaning to something that is worthy of the value we associate with the word.

The problem of counting options remains a difficulty for all the above theories. Berlin had earlier written that 'the method for counting [possibilities] can never be more than impressionistic. Possibilities of action are not discrete entities like apples, which can be exhaustively enumerated'

('Two Concepts of Liberty' 1958: 130fn1). But individuating possible actions is not the only problem for the philosopher who would apply quantitative measures to freedom's many dimensions, including comprehensiveness, fecundity, and diversity. And one does not exhaust the relevant possibilities by dividing all action into 'possible' and 'impossible.' There are also the component categories – difficult and easy, possible at great cost and possible at small cost, statistically probable and statistically improbable, multiple choices and either/or choices.

It is hard enough to deal with these problems of measurement, but they are almost equally difficult to evade, especially if we continue to speak of one individual or one society having more freedom than another. Moreover, if a philosopher maintains that both the number and the significance, importance or value of open options determines how free one is (and probably most philosophers take such a combination view), then the difficulties begin all over again when they leave off option-counting and begins option-evaluating.

FREEDOM, DIVINE

In the theistic tradition, many thinkers have held that God is infinitely powerful, all-knowing, perfectly good and perfectly free. But since a perfectly good being would invariably follow the best course of action, what can be meant when it is said that God acts freely? Two different views of divine freedom have emerged. According to the first view, God acts freely provided nothing outside him determines him to act. So when we consider God's action of creating a world, it is clear that on the first view he acts freely since there is nothing outside him to determine him to do as he does. The difficulty with this view is that it neglects the possibility that God's own nature might require him to create one particular world rather than another or none at all. According to the second view, God is free in an action provided it was within his power not to perform that action. Unlike the first view, on this view God acts freely only if nothing beyond God's control necessitates his performing that action. The problem for this view is that since it is impossible for God, being perfectly good, not to choose to follow the best course of action, it is difficult to see how God could be free in such an action.

FREEDOM OF SPEECH

Freedom of speech is one of the most widely accepted principles of modern political and social life. The three arguments most commonly offered in its defence are that it is essential for the pursuit of truth, that it is a fundamental constituent of democracy, and that it is a liberty crucial to human dignity and wellbeing. Its advocates also plead the dangers of allowing governments to control what may be said or heard. Yet there is also general agreement that speech should be subject to some limits. Most contemporary controversies about free speech concern those limits; some focus upon what should count as 'speech', others upon the harms that speech may cause.

PETER JONES

FREGE, GOTTLOB (1848–1925)

Introduction

A German philosopher-mathematician, Gottlob Frege was primarily interested in understanding both the nature of mathematical truths and the means whereby they are ultimately to be justified. In general, he held that what justifies mathematical statements is reason alone; their justification proceeds without the benefit or need of either perceptual information or the deliverances of any faculty of intuition.

To give this view substance, Frege had to articulate an experience- and intuition-independent conception of reason. In 1879, with extreme clarity, rigour and technical brilliance, he first presented his

conception of rational justification. In effect, it constitutes perhaps the greatest single contribution to logic ever made and it was, in any event, the most important advance since Aristotle. For the first time, a deep analysis was possible of deductive inferences involving sentences containing multiply embedded expressions of generality (such as 'Everyone loves someone'). Furthermore, he presented a logical system within which such arguments could be perspicuously represented: this was the most significant development in our understanding of axiomatic systems since Euclid.

Frege's goal was to show that most of mathematics could be reduced to logic, in the sense that the full content of all mathematical truths could be expressed using only logical notions and that the truths so expressed could be deduced from logical first principles using only logical means of inference. In this task, Frege is widely thought to have failed, but the attempted execution of his project was not in vain: for Frege did show how the axioms of arithmetic can be derived, using only logical resources, from a single principle which some have argued is, if not a logical principle, still appropriately fundamental. In addition, Frege contributed importantly to the philosophy of mathematics through his trenchant critiques of alternative conceptions of mathematics, in particular those advanced by John Stuart Mill and Immanuel Kant, and through his sustained inquiry into the nature of number and, more generally, of abstract objects.

In the course of offering an analysis of deductive argument, Frege was led to probe beneath the surface form of sentences to an underlying structure by virtue of which the cogency of inferences obtains. As a consequence of his explorations, Frege came to offer the first non-trivial and remotely plausible account of the functioning of language. Many of his specific theses about language – for instance, that understanding a linguistic expression does not consist merely of knowing which object it refers to – are acknowledged as of fundamental importance even by those who reject them.

More generally, three features of Frege's approach to philosophical problems have shaped the concerns and methods of analytic philosophy, one of the twentieth century's dominant traditions. First, Frege translates central philosophical problems into problems about language: for example, faced with the epistemological question of how we are able to have knowledge of objects which we can neither observe nor intuit, such as numbers, Frege replaces it with the question of how we are able to talk about those objects using language and, once the question is so put, avenues of exploration previously invisible come to seem plausible and even natural. Second, Frege's focus on language is governed by the principle that it is the operation of sentences that is explanatorily primary: the explanation of the functioning of all parts of speech is to be in terms of their contribution to the meanings of full sentences in which they occur. Finally, Frege insists that we not confuse such explanations with psychological accounts of the mental states of speakers: inquiry into the nature of the link between language and the world, on the one hand, and language and thought, on the other, must not concern itself with unsharable aspects of individual experience.

These three guiding ideas – lingua-centrism, the primacy of the sentence, and anti-psychologism – exercised a commanding influence on early analytic philosophers, such as Wittgenstein, Russell and Carnap. Through them, these ideas have been spread far and wide, and they have come to create and shape analytic philosophy, with whose fathering Frege, more than anyone else, must be credited.

1 Life and work

Gottlob Frege, a German philosopher and mathematician, is the father of modern logic and one of the founding figures of analytic philosophy. Trained as an algebraic geometer, he spent his professional life at the University of Jena, where, because his views about logic, mathematics and language were generally at odds with the dominant trends of the time, he laboured independently on his central philosophical project.

Frege's main work consists of his *Begriffsschrift* (*Conceptual Notation*) (1879), in which he first presents his logic; *Die Grundlagen der Arithmetik* (*The Foundations of Arithmetic*) (1884), in which he outlines the strategy he is going to employ in reducing arithmetic to logic and then goes on to provide the reduction with a philosophical rationale and justification; *Grundgesetze der Arithmetik* (*Basic Laws of Arithmetic*) (volumes 1, 1893, and 2, 1903), in which he seeks to carry out the programme in detail (a planned third volume was aborted following Bertrand Russell's communication to Frege in

1902 of his discovery of paradox in Frege's logic); and a series of philosophical essays on language, the most important of which are *Funktion und Begriff* ('Function and Concept') (1891), 'Über Sinn und Bedeutung' ('On Sense and Reference') (1892), 'Über Begriff und Gegenstand' ('On Concept and Object') (1892) and 'Der Gedanke: eine logische Untersuchung' ('Thoughts') (1918).

In general, Frege was not philosophically intrigued by what was specific to the human condition; for instance, he sought neither to probe the nature and limits of human knowledge nor to understand how humans actually reason. Yet he pursued his non-parochial philosophical interests by attending carefully to natural language and to the way it serves to express our thoughts. Frege's approach, in conjunction with his powerful tool of linguistic analysis (logic) and the collection of subtle, innovative and interwoven theses about language which he elaborated, spurred in others not only an intense interest in language as an object of inquiry but also adherence to a distinctive methodology which has come to characterize much analytic philosophy past and present.

2 Language and ontology

Frege's short book *Begriffsschrift* revolutionized the study of deductive inference. In the course of explaining how his 'conceptual notation' relates to natural language, Frege illuminates important features of language's underlying structure. He recognized that traditional grammatical categories have no logical significance and he urged the consideration instead of the categories of 'singular terms' (which he calls 'proper names') and of 'predicates' (which he calls 'concept-words'). For Frege, a singular term is a complete expression, one which contains no gaps into which another expression may be placed; for example, 'Virginia Woolf', 'the third planet from the Sun' and 'the largest prime number' are all singular terms according to Frege.

By contrast, a predicate such as '( ) was written by Virginia Woolf' is something incomplete; it is a linguistic expression which contains a gap and which becomes a sentence once this gap is filled by a singular term. (The parentheses are not part of the predicate but are intended only to indicate the location of the gap.) Thus, if we fill the gap with 'the third planet from the Sun', we get a complete sentence. This example shows that the resulting sentence may be false or perhaps even nonsense; what is important is that a complete sentence does result. Other examples of predicates are 'Leonard Woolf married ( )', '( ) orbits Jupiter' and '( ) is an even prime number greater than two'; there are infinitely many predicates in any natural language.

Frege distinguishes more finely between predicates, depending on how many gaps they contain and on the types of linguistic expressions that can fill them. The predicates we have so far considered each have just one gap and are known as 'one-place' predicates. '( ) is the mother of ( )' is an example of a 'two-place' predicate, for it contains two gaps, each to be filled by a singular term. Predicates whose gaps are to be filled by one or more singular terms, as is the case with all those mentioned so far, are said to be 'first-level'. Predicates whose gaps are to be filled by first-level predicates are said to be 'second-level', and so on. For example, when properly analysed, 'All [ ] are mammals' is seen to be a second-level predicate: its structure is really 'Everything is such that if it [ ], then it is a mammal', which makes it plainer that the gap is to be filled by a predicate of first-level. (We use square brackets to distinguish such gaps, which must be filled by first-level predicates, from those occurring in first-level predicates, which must be filled by singular terms.) And, for Frege, 'There is at least one thing which [ ]' is likewise a second-level predicate: as we shall see in a moment, this corresponds to his view that existence is not a concept that applies to objects but rather to concepts. This finer classification will not be discussed further here. Nor will the issue of how precisely to understand the incompleteness of predicates, and the corresponding completeness of singular terms, a question that continues to be debated.

The following two points, however, are not in dispute: first, Frege discerns in the categories of reality counterparts to the linguistic categories of singular term and predicate; he calls these ontological categories 'object' and 'concept', respectively. Second, Frege understands concepts on the model of functions as they are commonly encountered in mathematics.

A singular term refers to, or designates, an object. A predicate refers to, or designates, a concept. (We shall use 'designate' and 'refer' and their cognates interchangeably; in some discussions of Frege, 'denote' and 'mean' are also used.) Corresponding to the fact that a first-level predicate yields a complete sentence upon its gap being filled by a singular term, we have the fact that a first-level concept is true or false of an object – or, as Frege puts it, that an object 'falls under' or fails to fall under a concept. For this reason, Frege calls concepts 'unsaturated': unlike objects, they await completion, whereupon they yield one of the two truth-values, which Frege takes to be objects: the True and the False (see 'Function and Concept'). For example, the concept designated by '( ) is an Oxonian' yields the value the False when completed with the object designated by 'Gottlob Frege' and

the value the True when completed with the object designated by 'John Locke'.

Concepts are incomplete in the way that functions in mathematics are. For example, the function designated by '2 + ( )' yields the value 8 when completed with the object 6, or, as we might more simply say, it yields that value for the argument 6. The function '2 + ( )' is not an object, but yields one upon completion by an argument. On Frege's view, concepts are a kind of function, namely those that take as their only values the True or the False.

In describing this congruence of linguistic and ontological categories, Frege is not confusing use and mention (see USE/MENTION DISTINCTION AND QUOTATION); indeed, Frege exhibited an understanding of the distinction between words and what they designate not witnessed again until well into the twentieth century. Though linguistic expressions are claimed to slot into a certain set of categories and reality into another, an intimate connection obviously exists between the two categorial schemes. Whether Frege takes the linguistic scheme or instead the ontological one as fundamental is a subject of debate and bound up with the question of whether and in what sense Frege sees philosophical reflection on language as the foundation of philosophy.

Regardless of this debate's resolution, we know that Frege takes the categories of concept and object to be fundamental ontologically, ones not amenable to further analysis. In addition, basic structural features of language raise insurmountable obstacles to expressing certain truths about these categories. This can be demonstrated by considering the obvious claim (1) seeks to articulate:

(1) The concept designated by '( ) is a horse' is a concept.

This seems patently correct. Yet Frege recognizes in 'On Concept and Object'(1892) that we must judge (1) to be false. This is because the expression 'The concept designated by ( ) is a horse' is a singular term and hence refers to an object, not to a concept. (The expression does not contain a gap, though it does mention one.) So (1) does not succeed in expressing what we intended. To do this, we need to fill the gap in '( ) is a concept' by an expression that refers to a concept. But the straightforward way of doing this yields (2):

(2) ( ) is a horse is a concept,

which is not even a sentence. In trying to articulate our thought, we are led either to falsity or to something that makes no claim at all. This 'awkwardness of language', as Frege calls it, has been the subject of much controversy, but it seems clear that Frege draws the lesson that there are elemental facts about language and the world that perforce escape expression.

3 Sense and reference

How do what words refer to (concepts and objects) relate to our understanding of language? In his seminal essay 'On Sense and Reference' (1892), Frege considered whether the 'sense' of an expression – what it is that we know when we understand the expression – is simply identical to what it designates (the 'reference'). Frege offers the following argument, as famous as it is simple, to show that our understanding of singular terms cannot consist just of knowing their reference:

(3) (a) If two singular terms t and t' have the same sense and C is any (first-level) predicate, then $C(t)$ has the same sense as $C(t')$.

(b) 'The evening star = the morning star' does not have the same sense as 'The evening star = the evening star'.

(c) 'The evening star' does not have the same sense as 'the morning star'.

[This follows from (a) and (b): let C in (a) be 'The evening star = ( )'.]

(d) 'The evening star' refers to the same object as 'the morning star'.

(e) The reference of 'the evening star' is not identical with its sense.

[This follows from (c) and (d).]

So the sense of an expression – that which must be known in order for a speaker to understand it – cannot be identified with its reference (see SENSE AND REFERENCE). (A terminological digression: in this essay of 1892, Frege used the words '*Sinn*' and '*Bedeutung*', respectively. There is, however, no consensus on how these should be rendered in English. More importantly, there is not yet agreement about how precisely to understand these notions and how they are related to more everyday notions, such as meaning.)

Frege's justification for premise (a) relies on a 'compositionality thesis': the sense of a sentence is determined by the senses of its components (and by the way in which the sentence is constructed from them; see COMPOSITIONALITY). Premise (b) is justified by noting that an alert speaker would find the one sentence obvious, but not the other: 'The evening star = the evening star' is an uninformative statement of self-identity, whereas 'The evening star = the morning star' may impart hitherto unsuspected information. This difference in what Frege

called ‘cognitive value’ suffices, according to him, to register distinct senses. Finally, premise (d) follows from the observation that both singular terms designate the planet Venus, an astronomical discovery that was not made for some time.

If sense is not reference, then what is it? To this, Frege provides no clear answer. He writes in ‘On Sense and Reference’ that the sense of an expression is ‘the mode of presentation of that which is designated’, but he does not offer any elaboration regarding the nature of these modes (see PROPER NAMES). Frege does, however, advance a number of other theses concerning the relation between sense and reference. In the first place, the sense of an expression determines the identity of its reference, but not vice versa. For instance, the expression ‘the author of *Begriffsschrift*’ designates a particular individual, Frege, and any expression with the same sense designates the same individual; yet the expression ‘the author of *Die Grundlagen der Arithmetik*’, which also refers to Frege, has a different sense. Likewise, though ‘George Orwell’ and ‘Eric Blair’ both designate the same person (they have the same reference), the two singular terms have distinct senses.

Second, expressions can be formed which, while possessing a sense, lack a reference. For example, ‘Sherlock Holmes’ is a singular term that has a sense but lacks a reference, for Holmes does not exist. This is not in conflict with saying that sense determines reference, for what this means is that if two expressions have the same sense, then they have the same reference. One might wonder, though, whether this thesis is at odds with Frege’s description of sense as the way ‘that which is designated’ is presented: how can there be such a way when that which is designated, the reference, does not exist?

Many have found in the distinction between sense and reference relief from the philosophical distress that follows upon assuming, first, that we understand an expression by directly associating a reference with it and, second, that we understand expressions that fail to refer. Holding both of these assumptions has led philosophers to extravagant claims about the reality that is actually designated by our expressions, for instance that Holmes must exist in some fashion if we are to speak of him intelligibly (if only to deny his existence). Frege’s distinction between sense and reference, and his thesis that an expression can have a sense while lacking a reference, simply dissolves the problem by rejecting the first assumption (see DESCRIPTIONS).

The argument (3) concerns singular terms, but Frege believed that other kinds of expressions have sense and reference. The distinction can also be drawn in the case of predicates:

(4) Something is a bottle of claret if and only if it is a bottle of claret.

(5) Something is a bottle of claret if and only if it is a bottle of Hume’s favourite wine.

(4) does not have the same sense as (5): no one would deny the first, but the second might come as something of a gastronomic discovery. Though ‘( ) is a bottle of claret’ and ‘( ) is a bottle of Hume’s favourite wine’ are predicates that refer to the same concept, they have different senses. (Frege identifies two concepts if an object falls under the one if and only if it falls under the other.)

What is the reference of a whole sentence? Frege answers this by observing what remains unchanged about a sentence when we substitute coreferring expressions (that is, expressions that have the same reference) in it. Assuming a compositionality thesis for reference (that the reference of a sentence is determined by the reference of its components), we then have some reason to take whatever remains unchanged to be the sentence’s reference. Consider (6) and (7):

(6) George Orwell wrote *1984*.

(7) Eric Blair wrote *1984*.

What remains unchanged? Not the ‘thought’ expressed by each sentence: someone might believe one sentence to be true, but not the other. Rather, it is the truth-value of the sentences that is constant: (6) and (7) are either both true or both false. This leads Frege to identify the reference of a sentence with its truth-value; a sentence refers to one of the two truth-values. Frege takes the two truth-values to be objects and he observes that on his view all true (false) sentences are really singular terms that refer to the same object, the True (the False).

Because the sciences are interested in what is true, we can see why Frege holds that reference ‘is thus shown at every point to be the essential thing for science’ (‘Ausführungen über Sinn und Bedeutung’ 1892–5). Natural language permits the formation of expressions that lack reference, and so Frege judged it unsuitable as a tool of rational inquiry. For this purpose, it was inferior to his *Begriffsschrift*, a formal language he designed with the intention that no expression without reference could be constructed in it.

Frege notes that if his thesis that the reference of a sentence is its truth-value is correct, then we would predict (again on the basis of the compositionality thesis for reference) that if a subordinate sentence is replaced by a coreferential one (which will have the same truth-value), the reference of the entire containing sentence (that is, its truth-value) will remain unchanged. For instance, consider:

(8) Ronald Reagan was elected President in 1984 and George Orwell wrote *1984*.

(9) Ronald Reagan was elected President in 1984 and Eric Blair wrote *1984*.

(8) and (9) have the same truth-value, as predicted if the reference of a sentence is its truth-value. But now consider:

(10) Stimpson believes that George Orwell wrote *1984*.

(11) Stimpson believes that Eric Blair wrote *1984*.

If Stimpson does not realize that George Orwell and Eric Blair are one and the same person, (10) and (11) might have different truth-values, that is, they might differ in reference. And yet one is obtained from the other merely through substitution of what, on Frege's hypothesis, are the coreferring sentences (6) and (7).

Frege defends his hypothesis by claiming that in certain contexts expressions refer not to their ordinary reference but rather to an 'indirect' reference. And, he adds, the indirect reference of an expression is just its ordinary sense. Because 'Stimpson believes that ( ) wrote 1984' is just such a context and because 'George Orwell' has a different sense from 'Eric Blair' (and so, in this context, a different reference), the compositionality thesis for reference no longer forces us to the conclusion that (10) and (11) have the same truth-value. Frege's response inaugurated a long, fruitful and continuing debate about the nature of such linguistic contexts. (For further discussion, see Indirect discourse; Sense and reference.)

And what about the sense of a complete sentence? Given the compositionality thesis for sense, it will be preserved upon substitution of one expression in a sentence by another with identical sense. Frege says that such a substitution preserves the thought expressed by the sentence and he consequently identifies this thought with the sentence's sense. So, because 'to lie' has the same sense as 'to express something one believes to be false with the intention of deceiving', Frege would predict that the following two sentences express the same thought:

(12) Everyone has lied.

(13) Everyone has expressed something he believes to be false with the intention of deceiving.

And this prediction does seem to be borne out. But what precisely is the thought expressed by a sentence?

4 Thought and thinking

When one thinks the thought that lemons are sour, many different kinds of psychological events may transpire; certain memories, images or sensations may be triggered. These events, according to Frege, belong to the psychological world of the subject and, as such, are not fully shareable with others: much as one may try, one cannot experience what another does. It is a serious error, Frege says, to confuse such private events as may accompany our grasping of a thought with the thought that is grasped. One commits the sin of 'psychologism' if one does not sharply distinguish between the psychological process of thinking and the thoughts that are, as a consequence of this private activity, apprehended.

Thoughts then, in contrast to what Frege calls 'ideas', are fully shareable. When you and I grasp the sense of 'Lemons are sour', we arrive at the very same thought: there are not two different, related thoughts (as we might, for example, have two different mental images of lemons), but just the one that, through perhaps idiosyncratic and private paths, we both succeed in apprehending. And so it is in general with senses: they are not of the mental world but are objective in that different individuals can grasp them and associate them with their words. To stray from this perspective, according to Frege, is simply to abandon the view that communication is possible; that two speakers can understand a linguistic expression in the same way.

To grasp a thought is not to hold it true. For though one grasps a thought in the course of asserting it, it is no less grasped in the acts of assuming it to be true, wishing that it were true, commanding that it be made true, questioning whether it is true, and so on. These acts correspond to the different kinds of 'force' that may be attached to a thought. This is not quite Frege's position, but it is an influential one closely related to his views as given in 'On Sense and Reference'. It has been attractive to many students of language because it divides the daunting project of giving an explanation of linguistic understanding and use into two potentially more tractable components. The first task, the articulation of a 'theory of sense' or 'theory of meaning', is to explain how the sense of a sentence is determined by the senses of its parts. The second task, the articulation of a 'theory of force' (sometimes also called 'pragmatics'), is to explain, taking for granted an account of the thoughts expressed by sentences, the different speech acts into which they may enter. For example, it falls to the theory of meaning to describe the content of 'Lemurs are native to London' and to show how that thought is determined by the senses

of the sentence's constituent components. It falls to the theory of force to discover what, beyond the apprehension of that thought, is involved in asking 'Are lemurs native to London?', in wishing 'Oh, would that lemurs were native to London!', and so on. Should the theory of force need to make reference to the mental states of agents, then it is not merely helpful to divide an account of linguistic understanding and use into these two components but, Frege would insist, essential if we are to keep psychology from intruding into an account of sense (see PRAGMATICS; SPEECH ACTS).

5 *Objectivity and privacy*

In the previous section, we saw that Frege insists on the objectivity of thoughts (and senses generally), intending by this that different speakers can attach the very same thoughts to their sentences. There is a second way in which Frege takes thoughts to be objective. To say that thoughts are shareable is compatible with saying that their existence and properties are dependent upon human activity. Frege's view seems to be that thoughts are also objective in that they exist independently of human activity. Thoughts are not created or shaped by the process of thinking; they exist regardless of whether we have apprehended them, regardless of whether we shall ever apprehend them. Thoughts await our grasp in somewhat the way that physical objects await our observation, though the latter are located in space and time whereas thoughts are not.

These two kinds of objectivity – shareability and independence – are taken by Frege to apply to truth as well, which he considers a property of thoughts. There are not different properties – say, 'true-for-you' and 'true-for-me' – which are private unto individuals. There is just one property, being true, which some thoughts have and others lack. Furthermore, whether a thought possesses this property is in no way dependent upon our capacity to recognize that it does. A thought's being true must be sharply distinguished from our believing it to be true or our being justified in taking it to be true. On Frege's view, the truth of a thought is not dependent upon our beliefs, not even upon our beliefs in some ideal epistemic situation. Truth is one thing, our recognition of truth something else entirely. This position regarding the independence of truth, present throughout Frege's writings, is a robust realist motif in his thought, the evaluation of which has occupied centre-stage of much contemporary philosophy of language (see REALISM AND ANTIREALISM §4).

Since on Frege's view a sentence is true if and only if it refers to the value the True, his realism amounts to saying that a sentence refers to what it does independently of our recognition of this fact. But a sentence refers to an object only via its sense (the thought it expresses), which is what determines its reference. And its sense is not something that it has independently of speakers (after all, an expression – like 'chat', for example – can have one sense in one language and another in another), but is associated with it through human activity. Putting all this together, we see that, according to Frege, humans associate senses with linguistic expressions – this is what their understanding of language consists of – on account of which those expressions take on references whose identity may remain forever unknown.

That such a realism should follow from the senses attached to expressions forces our attention not only to Frege's notion of sense but, relatedly, to his conception of what it is to grasp a sense and associate it with an expression. Frege's anti-psychologism with regard to sense is not extended by him to an account of the grasping of sense, for in his few remarks about the subject he appears to avow a psychological picture of the process of apprehending a thought, of judging it to be true and so on (see 'Logik' 1897). Given his view of the privacy of mental events, it might seem that for Frege one cannot always determine which thought another has associated with a sentence: not that one cannot apprehend the same thought as another (for one feature of the objectivity of thoughts, that they can be grasped by all alike, guarantees that one can); but that one cannot always ascertain that one has.

That a speaker's linguistic understanding might remain private is a view that has troubled many, especially those influenced by the work of Ludwig Wittgenstein (see PRIVATE LANGUAGE ARGUMENT). Michael Dummett, the most influential interpreter of Frege's philosophy (see Dummett 1973), argues that, while much remains of lasting value in Frege's views on language, they should be modified in such a way that not only must senses be graspable by all, something on which Frege already insists, but the attachment of senses to expressions must be accessible as well; that is, the nature of a speaker's linguistic understanding must be a thoroughly public affair (see PRIVATE STATES AND LANGUAGE). Once these modifications are made, Dummett claims, important consequences will follow about which senses can be coherently grasped: if the only intelligible senses are those the grasp of which is subject to public inspection, then we must be sceptical of any analysis of linguistic understanding in terms of senses that underwrite realism and we should instead consider seriously analyses employing senses that do not countenance the possibility of sentences being true independently of all potential human knowledge. Both Dummett's argument and

his assumptions have been disputed, and the controversy continues to be a lively one. This is not an issue about which Frege explicitly said much, but it is among the many deep debates on the nature of language and thought which his work has made possible.

6 Contributions to logic

Infamous for using a notation difficult to learn to read, Frege's *Begriffsschrift* is one of the greatest logical works ever written. (Its full title in English is *Conceptual Notation: a Formula Language, Modelled Upon That of Arithmetic, for Pure Thought*.) It contains a number of major innovations, two of which are of foundational importance for contemporary logic: a satisfactory logical treatment of generality and the development of the first formal system. *Begriffsschrift* also introduces (what are essentially) truth tables, contains Frege's definition of the ancestral (§9) and sows the seeds of his philosophy of language (§§2–5).

Let us first discuss Frege's treatment of generality, that is, his logical analysis of sentences containing such words as 'everything', 'something', 'no one' and the like. The foundation for this is Frege's predicate–singular term analysis of simple sentences (§2). Sentences such as 'Tony is alive' contain a singular term, 'Tony', and a predicate, '( ) is alive'. We can extend this analysis to such sentences as 'Everything is alive' by drawing 'upon [the formula language of] arithmetic'. In arithmetic, a sentence containing a variable, 'x', is taken to be true if and only if a true sentence results no matter what x is supposed to be. For example, '$x + 2 = 2 + x$' is true if and only if, no matter what x may be, $x + 2 = 2 + x$. So, if we allow the argument of '( ) is alive' to be a variable, the resulting sentence 'x is alive' may be taken to express the generalization of 'Tony is alive'; it will be true if and only if, no matter what x may be, x is alive. Similarly, 'Everything is not alive' may be represented as 'x is not alive'. For, given the convention just explained, this will be true if and only if, no matter what x may be, x is not alive. But, as a little experimentation will show (and as can be proven), it is impossible to represent such sentences as 'Not everything is alive', so long as we use variables in this way alone. Nor can one so express 'If everything is alive, then snow is black'. One could try to represent it as 'If x is alive, then snow is black'. But this actually represents 'Everything is such that, if it is alive, then snow is black' (§11).

What is required here is some way of confining the generality expressed by the variable to a part of the sentence. In his informal discussions, Frege uses the phrase 'no matter what x may be' to do this (for example, §12). We may then represent 'Not everything is alive' as 'It is not the case that, no matter what x may be, x is alive'; and 'If everything is alive, then snow is black' as 'If, no matter what x may be, x is alive, then snow is black'. The phrase 'no matter what x may be', and its placement in the sentence, is said to delimit the 'scope' of the variable (see SCOPE). Frege's most vital discovery is not that variables may be used to indicate generality, but that variables have scope; his most significant innovation, the development of a notation in which scope can be represented, that is, his introduction of the *quantifier*.

Frege's second fundamental contribution was his construction of the first formal system. A formal system, as Frege conceives it, has three parts: first, a highly structured 'language' in which thoughts may be expressed; second, precisely specified 'axioms', or basic truths, about the subject matter in question; and third, 'rules of inference' governing how one sentence may be inferred from others already established. Frege believed that there were a number of advantages to carrying out proofs in such formal systems, for example, that giving a proof in a formal system would better one's understanding of the proof, by revealing precisely what principles it employs. Suppose, for example, that one wants to show that a given theorem can be proven without using the axiom of choice: the obvious method would be to prove the theorem without using the axiom. But how can one be sure that the axiom has not tacitly been employed (as it was in Richard Dedekind's proof of Theorem 159 in *Was sind und was sollen die Zahlen?* in 1888)? Proving the theorem in a formal system makes this possible: the axioms which may be used are clearly specified and steps in the proof may be taken only in accordance with certain rules. (Compare the Preface of *Begriffsschrift* to *Die Grundlagen der trithmetik* §2. Formal systems are important in contemporary logic for related reasons.)

The formal system of *Begriffsschrift* does not actually live up to the standards Frege imposes upon it: not all its rules of inference are explicitly stated. However, this complaint cannot be made about the system presented in Part I of his *Grundgesetze der Arithmetik* (1893). (The first-order fragment of this system is complete; the second-order fragment is a formulation of standard, second-order logic.) The rigour of Frege's formulation was not equalled until Kurt Gödel's work in the early 1930s, almost forty years later.

It is arguable that Frege goes even further and, in *Grundgesetze*, presents a semantics for his system; that is to say, he attempts to explain, rigorously, how the formal system is to be interpreted; how its symbols are to be understood. Using these explanations, he attempts to prove that the axioms of the system, so interpreted, are true and that the rules of the system, so interpreted, preserve truth (that is, in

technical parlance, to prove the system's soundness). If these controversial claims are correct, then Frege may also be credited with having anticipated, to a limited extent, the development of model theory.

7 Die Grundlagen der Arithmetik: *three fundamental principles*

In the Preface to *Begriffsschrift*, Frege announced his interest in determining whether the basic truths of arithmetic could be proven 'by means of pure logic'. Kant's answer had been negative. According to Kant, the truths of arithmetic are synthetic a priori: for example, knowledge of '7 + 5 = 12' requires appeal to intuition (see KANT, I. §§4–5). One of Frege's main goals in his *Die Grundlagen der Arithmetik* (*The Foundations of Arithmetic*) was to refute this view by giving purely logical proofs of the basic laws of arithmetic, thereby showing that arithmetical truths can be known independently of any intuition. Frege conceived the formal system of *Begriffsschrift* as an important prerequisite for this project: without it, it would be impossible to determine whether the complex proofs required do indeed depend only upon axioms of 'pure logic'.

There has been some controversy about what motivated Frege's logicism – his view that the truths of arithmetic are truths of logic (see LOGICISM). Frege says that his project is inspired by both mathematical and philosophical concerns (§§1–3). Some, notably Paul Benacerraf, have defended the view that Frege was interested in philosophical problems only in so far as they were susceptible of mathematical resolution. However that may be, Mark Wilson and Jamie Tappenden have argued that there are important connections between Frege's work on arithmetic and then recent developments in geometry to which he would have been exposed during his graduate career.

Grundlagen is important for a number of reasons. The philosophy of arithmetic developed in the book is of continuing interest. Moreover, a large number of more specific theses propounded there have had a profound influence on later philosophers, including Ludwig Wittgenstein, W.V. Quine and Michael Dummett, to name but three. More generally, *Grundlagen* is arguably the first work of analytic philosophy. At crucial points in the book, Frege makes 'the linguistic turn': that is, he recasts an ontological or epistemological question as a question about language. Unlike some 'linguistic' philosophers, his purpose is not to dissolve the philosophical problem – to unmask it as a 'pseudo-problem' – but to reformulate it so that it can be solved.

According to Frege, his work in *Grundlagen* is guided by 'three fundamental principles' he states in the Preface:

> always to separate sharply the psychological from the logical, the subjective from the objective;
> never to ask for the meaning of a word in isolation, but only in the context of a proposition;
> never to lose sight of the distinction between concept and object.
>
> (1884: x)

All of these are sufficiently important to warrant separate discussion. The first, which announces Frege's opposition to 'psychologism', has been discussed in §§4–5; the second, which is called 'the context principle', will be discussed in §8 below.

The third principle, which distinguishes the sorts of things singular terms denote – objects – from the sorts of things predicates denote – concepts – has already been discussed in §2. Of present interest is the application Frege makes of this distinction in *Grundlagen* §§45–54. Just prior to these sections, Frege has been concerned with what numbers are, his results having been almost entirely negative: numbers are neither physical objects; nor collections or properties of such; nor subjective ideas. Frege now suggests that progress may be made by asking to what, exactly, number is ascribed. The crucial observation is that different numbers seem to be assignable to the same thing: of a pack of cards, for example, one could say that it was one pack or fifty-two cards. Frege realizes that this might suggest that ascription of number is subjective; dependent upon our way of thinking about the object in question (§§25–6). But what is different in our way of regarding the pack is, specifically, the 'concept' we choose to employ: that denoted by '( ) is a pack' in the one case, or by '( ) is a card' in the other. If, with Frege, we insist that concepts, and facts about them, can be just as objective as objects and facts about them (see also 'Function and Concept' §48), there is no need to regard number as subjective. Rather, we must acknowledge that number is ascribed not to objects, nor to collections thereof, but to concepts:

> If I say 'Venus has 0 moons', there simply does not exist any moon or agglomeration of moons for anything to be asserted of; but what happens is that a property is assigned to the *concept* 'moon of Venus', namely that of including nothing under it. If I say, 'the King's carriage is drawn by four horses', then I assign the number four to the concept 'horse that draws the King's carriage'.
>
> (§46; emphasis added)

(Note that we will use '"moon of Venus"' and '( ) is a moon of Venus' to denote the same concept.) As Frege famously puts the point in §55: 'the content

of a statement of number is an assertion about a concept'.

Observe here how Frege's interest in what numbers are has led him to an interest in the nature of ascriptions of number and, in particular, to an investigation of the 'logical form' of such statements. According to Frege, the most fundamental way of referring to a number is by means of an expression of the form 'the number belonging to the concept *F*'; for example, 'the number belonging to the concept "moon of the earth"' refers to the number one, for there is just one object that is a moon of the earth. This seemingly innocuous linguistic claim plays a crucial role in Frege's account of what numbers are.

8 Die Grundlagen der Arithmetik: *the context principle*

Frege denied both that numbers are physical objects and that they are objects of intuition, in Kant's sense. In *Grundlagen* §62, he therefore raises the question of how 'numbers [are] given to us, if we cannot have any ideas or intuitions of them'. This question is plainly epistemological, concerning how we can have knowledge of the objects (and so the truths) of arithmetic. What is astonishing is how Frege sets about answering it: 'Since it is only in the context of a proposition that words have any meaning, our problem becomes this: to define the sense of a proposition in which a number word occurs.' As Michael Dummett has emphasized, Frege here makes 'the linguistic turn' in a profound way: what was plainly an epistemological problem is converted into one about language. The question of how we can have knowledge about numbers becomes the question of how we refer to – that is, succeed in talking about – numbers.

Frege suggests that this question can be answered by examining whole sentences in which names of numbers occur. It is here that the second of Frege's fundamental principles, the context principle, is at work. Frege rejects any requirement that he should point out or, in some other way, display numbers for his audience. He has already asserted that this would be impossible, since numbers cannot be encountered in perception (we have no 'ideas' of them) or in intuition. Rather, Frege insists, one's ability to refer to numbers should be explained in terms of one's understanding of complete sentences in which names of numbers are employed. That is to say, Frege refuses to say what 'zero' refers to except to say what such sentences as 'Zero is the number belonging to the concept "moon of Venus"' mean. More precisely, he insists that to explain the meanings of such sentences is to say what 'zero' refers to.

Frege intends this view to be generalized: indeed, his own discussion of it does not concern numbers directly, but the analogous case of directions. So-called abstract objects pose serious philosophical problems, both ontological and epistemological. Frege's strategy for defending their existence and for defusing worries about our cognitive access to them is appealing and may well seem the only workable option. His general idea, that our capacity to refer to objects of a given kind may be explained only in terms of our understanding of sentences containing names of them, has been of continuing influence.

To return to our main thread, the immediate goal is to explain the meaning of sentences in which reference is made to numbers. Frege claims that, when we are concerned with names of *objects*, the most important such sentences are those asserting an identity. Because Frege takes numbers to be objects, he focuses upon such sentences as 'The number belonging to the concept "plate on the table" is the same as that belonging to the concept "guest at dinner"'. Frege observes that this sentence will be true if and only if there is a way of assigning plates to guests such that each guest gets exactly one plate, and each plate exactly one guest; that is, if and only if there is a one-to-one correlation between the plates and the guests. More generally, say that the concept *F* is equinumerous with the concept *G* if and only if there is a one-to-one correlation between the objects falling under *F* and those falling under *G*. Then the thought is this: the number belonging to the concept F = the number belonging to the concept *G* if and only if the concept *F* is equinumerous with the concept *G*. Since Frege introduces it with a quotation from Hume, this is sometimes called 'Hume's Principle' (1884: §§55–63). The principle had been known for some time, but it was only in the work of Georg Cantor that its mathematical significance was fully realized (see SET THEORY).

Of course, if Hume's Principle is to play any role in Frege's attempt to prove the axioms of arithmetic from logical principles alone, the notion of equinumerosity must be definable in purely logical terms. But Frege shows that it is, if the general theory of relations is accepted as part of logic (§§70–2).

For reasons which are not entirely clear, Frege rejects the claim that Hume's Principle suffices to explain numerical identities. His stated reason (§66; compare §56) is that it fails to decide whether Julius Caesar is the number zero! But there is little agreement about the point of this complaint or about its force. Still, Hume's Principle continues to be important to Frege, since he insists that any correct explanation of numbers must have Hume's Principle as a (relatively immediate) consequence.

He himself settles upon an explicit definition of names of numbers: the number belonging to the concept *F* is to be the extension of the second-level concept '[ ] is a concept equinumerous with the concept *F*'. (Roughly, the extension of a concept is the collection of things that fall under that concept.) Frege shows how Hume's Principle may be derived from this definition (§73). To make the definition and proof precise, however, he has to appeal to some axiom concerning extensions. Frege's idea, developed in *Grundgesetze*, was that extensions could be characterized by means of a principle analogous to Hume's Principle, namely, his Basic Law V: the extension of the concept *F* is the same as that of the concept *G* if and only if the very same objects fall under the concepts *F* and *G* (*Grundgesetze* §§3, 20). Famously and unfortunately, however, Bertrand Russell showed Frege, in 1902, that the resulting theory of extensions is inconsistent, since Russell's paradox can be derived from Basic Law V in (standard) second-order logic (see Paradoxes of set and property).

9 Frege's formal theory of arithmetic

The story of Frege's work on arithmetic might well have ended there. In *Grundlagen*, Frege does sketch proofs of axioms for arithmetic (§§70–83) and, in *Grundgesetze*, offers formal versions of them (§§78–119). But little attention was paid to these proofs for almost a century, on the ground that Frege gave his proofs in an inconsistent theory, and anything can be proven in an inconsistent theory. Frege himself decided in about 1906 that no suitable reformulation of Basic Law V was forthcoming and, his wife having died in 1904, appears to have become deeply depressed. He published nothing at all between 1908 and 1917 and only three further articles after that.

Closer attention to the structure of Frege's proofs reveals something interesting, however. As already stated, Frege requires that his explicit definition of names of numbers imply Hume's Principle, and he shows that it does (given Basic Law V). But neither the explicit definition nor Basic Law V is used essentially in the proof of any other arithmetical theorem; these other theorems are proven using only second-order logic and Hume's Principle. Thus, Frege in fact proves that axioms for arithmetic can be derived in second-order logic from Hume's Principle alone. Frege himself knew as much, but, sadly, never appreciated the philosophical and mathematical significance of this result, now known as Frege's Theorem.

The details of Frege's proof of this result are beyond the scope of this discussion. But a few points are worth mentioning. First, one cannot actually prove each of the infinitely many truths of arithmetic from logical principles, or from anything else. So any attempt to show that all truths of arithmetic follow from logical principles, or from Hume's Principle, will depend upon the identification of some finite number of basic laws, or axioms, of arithmetic from which we are confident all other arithmetical truths will follow. The most famous such axioms are those due to Dedekind (though widely known as the Peano axioms). Frege employs his own axiomatization which, while similar, is importantly different and arguably more intuitive (*Grundgesetze*: §§128–57).

Second, Frege's hardest task is to prove that there are infinitely many numbers, and his method of doing so is extremely elegant. The basic idea is as follows. Begin by noting that 0 is the number belonging to the concept 'object not the same as itself' and then that 1 is the number belonging to the concept 'identical with 0'. Further, 2 is the number belonging to the concept 'identical with 0 or 1', and so on. More generally, if *n* is finite, then the number of the concept 'natural number less than or equal to *n*' is always one more than *n*, which implies that every finite number has a successor and (in the presence of the other axioms) that there are infinitely many numbers (*Grundlagen*: §§82–3; *Grundgesetze*: §§114–19).

Third, Frege needs, for a variety of reasons, to define the notion of a finite, or natural, number. He also needs to prove the validity of proof by induction, since one of his (and Dedekind's) axioms is, essentially, that such proofs are legitimate. Induction is a way of proving that all natural numbers fall under a concept *F*; a proof by induction proceeds by showing (1) that 0 falls under *F* and (2) that, if a number *n* falls under *F*, $n + 1$ must also fall under *F*. In essence, Frege *defines* the natural numbers as those objects for which induction works. According to Frege's definition, a number is a natural number if and only if it falls under every concept *F* which is a concept (1′) under which 0 falls and (2′) which is 'hereditary in the number series', that is, under which $n + 1$ falls whenever *n* does. It then follows, immediately, that proof by induction is valid: if *F* is a concept satisfying (1) and (2), then, since *F* is then a concept satisfying (1′) and (2′), every natural number must fall under it, by definition.

It is possible to see, intuitively, that this is a good definition, that is, that what Frege calls 'the natural numbers', the things that fall under every concept satisfying (1′) and (2′), *really are* the natural numbers. Certainly, if *x* is a natural number, then it falls under every concept satisfying (1′) and (2′). Conversely, suppose that *x* falls under every concept satisfying (1′) and (2′). Well, the concept 'natural number' is

such a concept: for (1′′) 0 certainly falls under it, and (2′′) whenever a number *n* falls under it, $n + 1$ also falls under it. So, since *x* falls under *every* concept satisfying (1′) and (2′), it must fall under this one, that is, it must be a natural number. Thus, falling under every concept satisfying (1′) and (2′) is both necessary and sufficient for being a natural number. (Objections can be made to this argument, chiefly on the grounds of its 'impredicativity'.)

This method of definition may be generalized to furnish a definition of the 'ancestral' of any given relation. Frege's definition of the ancestral, introduced in *Begriffsschrift* (and independently discovered by Dedekind), is of quite general importance in mathematics.

Frege's formal work in *Grundgesetze* does not end with his proof of the arithmetical axioms. He goes on to develop purely logical definitions both of finitude and of infinitude; he proves the so-called categoricity theorem, that any two structures which satisfy his axioms for arithmetic are isomorphic; and he proves the validity of definition by induction. (These last two results were first proven by Dedekind.) There is also some reason to believe that Frege was interested in proving results now known to depend upon the axiom of choice and that his investigations led him to discover – though not to communicate – this axiom some years before Ernst Zermelo's formulation of it in 1904. Finally, in later parts of *Grundgesetze*, Frege proves a number of preliminary results required for a logicist development of the theory of real numbers, but a projected third volume, which would have completed that part of the project, was abandoned in the wake of Russell's paradox.

10 The fate of Frege's logicism

Frege proved Frege's Theorem, that is, that axioms for arithmetic are (second-order) logical consequences of Hume's Principle. Of course, this would be of little interest but for the fact that, unlike Basic Law V, Hume's Principle is consistent. If, therefore, Hume's Principle could be argued to be a truth of logic, then the truths of arithmetic, being logical consequences of a truth of logic, would all be truths of logic and logicism would be vindicated! Work on Frege's philosophy of arithmetic has therefore tended to abstract from Frege's ill-fated explicit definition and to concern itself with the view Frege himself rejected, namely that names of numbers may be defined, or explained, by means of Hume's Principle.

No one nowadays really thinks that Hume's Principle is a truth of logic. Still, one might think that Hume's Principle is suitable as some kind of definition, or philosophical explanation, of names of numbers. And, or so argues Crispin Wright, if the truths of arithmetic turn out to be logical consequences of an explanation, is that not almost as good as if they were truths of logic? This view is appealing precisely because Hume's Principle does seem to capture something very fundamental about (cardinal) numbers: saying that the number belonging to the concept *F* is the same as that belonging to *G* if and only if the concepts *F* and *G* are equinumerous just does seem a good way of explaining what (cardinal) numbers are. Still, there are serious worries. Saying that the extension of *F* is the same as the extension of *G* if and only if the same objects fall under *F* and *G* also *seems* to be a good way of explaining what extensions are – until one realizes this explanation is inconsistent. Hume's Principle is not inconsistent, of course, but one might wonder whether it can rightly be viewed as explanatory of what numbers are if such a kindred principle cannot rightly be viewed as explanatory of what extensions are. It is in the debate over this, the 'bad company objection' raised by George Boolos and Michael Dummett, that the fate of Frege's logicism will be decided.

ALEXANDER GEORGE
RICHARD HECK

FREUD, SIGMUND (1856–1939)

Freud developed the theory and practice of psychoanalysis, one of the most influential schools of psychology and psychotherapy of the twentieth century. He established a relationship with his patients which maximized information relevant to the interpretation of their behaviour, and this enabled him to find explanations of dreams, symptoms and many other phenomena not previously related to desire. In consequence he was able

radically to extend our common-sense psychology of motive.

On Freud's account everyday actions are determined by motives which are far more numerous and complex than people realize, or than common-sense understanding takes into account. The most basic and constant motives which influence our actions are unconscious, that is, difficult to acknowledge or avow. Such motives are residues of encounters with significant persons and situations from the past, often reaching back to early childhood; and they operate not to achieve realistic satisfaction, but rather to secure a form of pacification through representation. When we interpret what others say and do, we apply these patterns of satisfaction and pacification to explain their behaviour; and in so far as we succeed in understanding others in this way we support the patterns as empirical generalization. While we recognize that pacification consequent on genuine satisfaction is deeper and more lasting than that effected by representation alone, we also know that human desire outruns opportunities for satisfaction to such an extent that pacification via imagination is common. This is a view which psychoanalysis radically extends.

This understanding of the mind enabled Freud to give psychological accounts of neurosis and psychosis, and to explicate how the past gives significance to the present in normal mental functioning. Past desires, even those of infancy, are not psychologically lost; rather they are continually re-articulated through symbolism, so as to direct action towards their representational pacification throughout life. In this Freud provides both a radically holistic account of the causation of action and a naturalistic description of the generation of meaning in life. New goals acquire significance as representatives of the unremembered objects of our earliest and most visceral passions; and the depth of satisfaction we feel in present accomplishments flows from their unacknowledged pacification of unknown desires from the distant past. Thus, paradoxically, significant desires can remain forever flexible, renewable and satisfiable in their expressions, precisely because they are immutable, frustrated and unrelenting at the root.

FRIENDSHIP

Philosophical interest in friendship has revived after a long eclipse. This is due largely to a renewed interest in ancient moral philosophy, in the role of emotion in morality, and in the ethical dimensions of personal relations in general. Questions about friendship are concerned with issues such as whether it is only an instrumental value (a means to other values), or also an intrinsic value – a value in its own right; whether it is a mark of psychological and moral self-sufficiency, or rather of deficiency; and how friendship-love differs from the unconditional love of *agapē*. Other issues at stake include how – if at all – friendship is related to justice; whether the particularist, partialist perspective of friendship can be reconciled with the universalist, impartialist perspective of morality; and whether friendship is morally neutral.

FUNCTIONAL EXPLANATION

Explanations appealing to the functions of items are common in everyday discourse and in science: we say that the heart pumps blood because that is its function, and that the car fails to start because the ignition is not functioning. Moreover, we distinguish the functions things perform from other things they do: the heart makes a noise, but that is not one of its functions. Philosophical discussions in this area attempt to specify conditions under which it is appropriate to ascribe functions to items and under which it is appropriate to appeal to those functions in explanations. Difficulties arise because functions are normative: there is some sense in which items ought to perform their functions; failure to perform is a kind of error. Philosophical discussions investigate whether and how this normativity can be understood in scientifically respectable terms. This is important, because biological entities are among the most characteristically functional items. This issue gives rise to differing views as to what it is that functional explanations explain. One view is that they explain how a containing system achieves some goal or effect. Another is that functional explanations explain causally why the functional item exists.

RICHARD N. MANNING

FUNCTIONALISM

The term 'functionalism' means different things in many different disciplines from architectural theory to zoology. In contemporary philosophy of mind, however, it is uniformly understood to stand for the view that mental states should be explained in terms of causal roles. So, to take a simple example, a functionalist in the philosophy of mind would argue that pains are states which are normally caused by bodily damage, and tend in turn to cause avoidance behaviour.

Functionalism is often introduced by an analogy between mental states and mechanical devices. Consider the notion of a carburettor, say. For something to be a carburettor it need not have any particular physical make-up. Carburettors can come in many different materials and shapes. What makes it a carburettor is simply that it plays the right causal role, namely that it mixes air with petrol in response to movements of the accelerator and choke. Similarly, argue functionalists, with the mind. The possession of mental states does not depend on the physical make-up of the brain; it depends only on its displaying the right causal structure. Since organisms with very different sorts of biological make-up, like octopuses and humans, can have states with the causal role of pain, say, it follows from functionalism that octopuses and humans can both be in pain.

There exists a number of different subspecies of functionalism. One important division depends on how the relevant causal roles are determined. 'Common-sense' functionalists take them to be fixed by common-sense psychology; 'scientific' functionalists take them to be fixed by the discoveries of scientific psychology. So, for example, common-sense functionalists will hold that emotions play the causal role that common-sense psychology ascribes to emotions, while scientific psychologists will argue that scientific psychology identifies this causal role.

Functionalism, of whatever subspecies, is open to a number of well-known criticisms. One central objection is that it cannot accommodate the conscious, qualitative aspect of mental life. Could not a machine share the causal structure of someone who was in pain, and thereby satisfy the functionalist qualification for pain, and yet have no conscious feelings?

It might seem that functionalists can respond to this difficulty by being more stringent about the requirements involved in the causal role of a given human sensation. But there is a danger that functionalism will then lose much of its appeal. The original attraction of functionalism was that its 'liberal' specification of causal roles allowed that humans could share mental states with non-humans. This feature is likely to be lost if we switch to more 'chauvinist' specifications designed to explain why non-humans do not share our conscious life.

Another objection to functionalism is that it cannot account for mental representation. Functionalism focuses on the way mental states enter into causal structure. But it is doubtful that mental representation can be explained in purely causal terms.

Some philosophers argue that the issue of mental representation can be dealt with by adding some teleology to functionalism, that is by considering the biological purposes for which mental states have been designed, as well as their actual structure of causes and effects. However, once we do appeal to teleology in this way, it is not clear that we still need a functionalist account of representational states, for we can now simply identify such states in terms of their biological purposes, rather than their causal roles.

DAVID PAPINEAU

FUTURE GENERATIONS, OBLIGATIONS TO

There are at least three different views concerning obligations to future generations. One is that morality does not apply here, future generations not being in any reciprocal relationship with us. Another is that, though we are not obliged to do anything for future generations, it would be praiseworthy to do so. A third view is that justice demands that we respect the interests of future generations.

Philosophers and others have discussed obligations in three main areas: the environment, and the damage inflicted upon it in pursuit of profit; savings and the accumulations of capital; and population policy.

Different theoretical approaches have been taken. According to utilitarianism, the interests of future people count equally with those of present people, and all interests are to be satisfied maximally. This may have very demanding implications. Contractarianism rests morality on the agreement of all affected parties. But whose views will be considered in the case of future generations? Perhaps the most plausible approach is communitarianism, according to which obligations can rest on a sense of community which stretches into the future.

AVNER DE-SHALIT

FUZZY LOGIC

The term ‘fuzzy’ refers to concepts without precise borders. Membership in a ‘fuzzy’ set – the set of things to which a ‘fuzzy’ concept (fuzzily) applies – is to be thought of as being a matter of degree. Hence, in order to specify a fuzzy set, one must specify for every item in the universe the extent to which the item is a member of the set. The engineer Lotfi Zadeh developed a theory of fuzzy sets and advocated their use in many areas of engineering and science. Zadeh and his zealous followers have attempted to develop fuzzy systems theory, fuzzy algorithms and even fuzzy arithmetic. The phrase ‘fuzzy logic’ has come to be applied rather imprecisely to any analysis that is not strictly binary. It does not refer to any particular formal logic, in the sense in which the term ‘logic’ is used by philosophers and mathematicians. (‘Fuzzy logic’ is sometimes used anachronistically to refer to any many-valued logic.)

CHARLES G. MORGAN

G

GADAMER, HANS-GEORG (1900–2002)

Hans-Georg Gadamer is best known for his philosophical hermeneutics. Gadamer studied with Martin Heidegger during his preparation of *Being and Time* (1927). Like Heidegger, Gadamer rejects the idea of hermeneutics as merely a method for the human and historical sciences comparable to the method of the natural sciences. Philosophical hermeneutics is instead about a process of human understanding that is inevitably circular because we come to understand the whole through the parts and the parts through the whole. Understanding in this sense is not an 'act' that can be secured methodically and verified objectively. It is an 'event' or 'experience' that we undergo. It occurs paradigmatically in our experience of works of art and literature. But it also takes place in our disciplined and scholarly study of the works of other human beings in the humanities and social sciences. In each case, understanding brings self-understanding.

Philosophical hermeneutics advocates a mediated approach to self-understanding on the model of a conversation with the texts and works of others. The concept of dialogue employed here is one of question and answer and is taken from Plato. Such understanding never becomes absolute knowledge. It is finite because we remain conditioned by our historical situation, and partial because we are interested in the truth that we come to understand. By grounding understanding in language and dialogue as opposed to subjectivity, Gadamer's philosophical hermeneutics avoids the danger of arbitrariness in interpreting the works of others.

Gadamer's most important publication is *Wahrheit und Methode* (Truth and Method) (1960). He also published four volumes of short works, *Kleine Schriften* (1967–77), containing important hermeneutical studies of Plato, Hegel, and Paul Celan among others. His many books and essays are collected into ten volumes (*Gesammelte Werke*). Gadamer was widely known as a teacher who practised the dialogue which is at the core of his philosophical hermeneutics.

KATHLEEN WRIGHT

GALILEI, GALILEO (1564–1642)

Galileo Galilei, one of the most colourful figures in the long history of the natural sciences, is remembered best today for two quite different sorts of reason. He has often been described as the 'father' of modern natural science because of his achievements in the fields of mechanics and astronomy, and for what today would be called his philosophy of science, his vision of how the practice of science should be carried on and what a completed piece of natural science should look like. While none of the elements of that philosophy was entirely new, the way in which he combined them was so effective that it did much to shape all that came after in the sciences. In the popular mind, however, as a continuing stream of biographies attest, it is his struggle with Church authority that remains the centre of attention, symbolic as it is of the often troubled, but always intriguing, relationship between science and religion.

GASSENDI, PIERRE (1592–1655)

Pierre Gassendi, a French Catholic priest, introduced the philosophy of the ancient atomist Epicurus into the mainstream of European thought. Like many of his contemporaries in the first half of the seventeenth century, he sought to articulate a new philosophy of nature to replace the Aristotelianism that had traditionally provided foundations for natural philosophy. Before European intellectuals could accept the philosophy of Epicurus, it had to be purged of various heterodox notions. Accordingly, Gassendi modified the philosophy of his ancient model to make it conform to the demands of Christian theology.

Like Epicurus, Gassendi claimed that the physical world consists of indivisible atoms moving in void space. Unlike the ancient atomist, Gassendi argued that there exists only a finite, though very large, number of atoms, that these atoms were created by God, and that the resulting world is ruled by divine providence rather than blind chance. In contrast to Epicurus' materialism, Gassendi enriched his atomism by arguing for the existence of an immaterial, immortal soul. He also believed in the existence of angels and demons. His theology was voluntarist, emphasizing God's freedom to impose his will on the Creation.

Gassendi's empiricist theory of knowledge was an outgrowth of his response to scepticism. Accepting the sceptical critique of sensory knowledge, he denied that we can have certain knowledge of the real essences of things. Rather than falling into sceptical despair, however, he argued that we can acquire knowledge of the way things appear to us. This 'science of appearances' is based on sensory experience and can only attain probability. It can, none the less, provide knowledge useful for living in the world. Gassendi denied the existence of essences in either the Platonic or Aristotelian sense and numbered himself among the nominalists.

Adopting the hedonistic ethics of Epicurus, which sought to maximize pleasure and minimize pain, Gassendi reinterpreted the concept of pleasure in a distinctly Christian way. He believed that God endowed humans with free will and an innate desire for pleasure. Thus, by utilizing the calculus of pleasure and pain and by exercising their ability to make free choices, they participate in God's providential plans for the Creation. The greatest pleasure humans can attain is the beatific vision of God after death. Based on his hedonistic ethics, Gassendi's political philosophy was a theory of social contract, a view which influenced the writings of Hobbes and Locke.

Gassendi was an active participant in the philosophical and natural philosophical communities of his day. He corresponded with Hobbes and Descartes, and conducted experiments on various topics, wrote about astronomy, corresponded with important natural philosophers, and wrote a treatise defending Galileo's new science of motion. His philosophy was very influential, particularly on the development of British empiricism and liberalism.

GENEALOGY

'Genealogy' is an expression that has come into currency since the 1970s, a result of Michel Foucault's works *Surveiller et punir* (1975) (*Discipline and Punish*, 1977) and *The History of Sexuality* (1976, 1984). Foucault's use of the term continues Nietzsche's in his *On the Genealogy of Morals* (1887). For both philosophers, genealogy is a form of historical critique, designed to overturn our norms by revealing their origins. Whereas Nietzsche's method relies on psychological explanations, and attacks modern conceptions of equality in favour of a perfectionist ethic, Foucault's relies on microsociological explanations, and attacks modern forms of domination in favour of radical politics.

R. KEVIN HILL

GENERAL WILL

The fundamental claim for general will is that the members of a political community, as members, share a public or general interest or good which is for the benefit of them all and which should be put before private interests. When the members put the general good first, they are willing the general will of their community. The claim was given special and influential shape by Rousseau. He produced a comprehensive theory of the legitimacy of the state and of government, revolving around the general will. Some contend this solves the central problem of political philosophy – how the individual can both be obliged to obey the state's laws, and be free. If laws are made by the general will, aimed at the common good and expressed by all the citizens, the laws must be in accordance with the public interest and therefore in the interest of each, and each is obliged by the law yet free because they are its author. Rousseau's formulation has been much criticized. But others have found it essentially true and have variously adapted it.

PETER P. NICHOLSON

GENETIC MODIFICATION

Genetic modification is the heritable alteration of the genetic make-up of an organism. As a natural process this is as old as genes themselves, and has been utilized by human beings since the beginnings of agriculture. Recently, the term has come to apply specifically to newly developed DNA technologies, where the genome of an organism is modified using artificial techniques. These rely on the ability to cut DNA precisely, isolate desired fragments and insert them into a single cell of another organism. From this transformed cell a new multicellular organism can be regenerated. There is a wide range of applications of the new technology, from employing yeast to synthesize human insulin, to making crops resistant to pest and diseases. However, it has also attracted much opposition. It has been criticized for being unnatural, for posing an unassessable risk to the environment and to human health, and for providing an instrument for, the manipulation of human genetic make-up that might invite serious abuse.

EDWARD CRAIG

GENETICS

Genetics studies the problem of heredity, namely why offspring resemble their parents. The field emerged in 1900 with the rediscovery of the 1865 work of Gregor Mendel. William Bateson called the new field 'genetics' in 1905, and W. Johannsen used the term 'gene' in 1909. By analysing data about patterns of inheritance of characters, such as yellow and green peas, Mendelian geneticists infer the number and type of hypothetical genes. The major components of the theory of the gene, which proposed the model of genes as beads on a string, were in place by the 1920s. In the 1930s, the field of population genetics emerged from the synthesis of results from Mendelian genetics with Darwinian natural selection. Population geneticists study the distribution of genes in the gene pool of a population and changes caused by selection and other factors. The 1940s and 1950s saw the development of molecular genetics, which investigates problems about gene reproduction, mutation and function at the molecular level.

Philosophical issues arise: the question about the evidence for the reality of hypothetical genes, and the status of Mendel's laws, given that they are not universal generalizations. Debates have occurred about the nature of the relation between Mendelian and molecular genetics. Population genetics provides the perspective of the gene as the unit of selection in evolutionary theory. Molecular genetics and its accompanying technologies raise ethical issues about humans' genetic information, such as the issue of privacy of information about one's genome and the morality of changing a person's genes. The nature–nurture debate involves the issue of genetic determinism, the extent to which genes control human traits and behaviour.

LINDLEY DARDEN

GENETICS AND ETHICS

The identification of human genes poses problems about the use of resources, and about ownership and use of genetic information, and could lead to overemphasis of the importance of genetic make-up. Genetic screening raises problems of consent, stigmatization, discrimination and public anxiety. Counselling will be required, but whether this can facilitate individual choice is unclear. It will also involve problems of confidentiality. On the other hand genetic knowledge will pave the way for genetic therapies for hereditary disease. This raises the question whether a therapy which alters an individual at the genetic level is different in kind from conventional medical treatment. Genetic alterations passed on to future generations raise problems regarding consent. Genetic intervention could also be used to make 'improvements' in human genetic potential, leading to anxieties about eugenic attempts to design the species. Transgenics, the introduction of foreign genes into a genome, raises questions about the integrity of species boundaries and the assessment of risk.

RUTH CHADWICK

GENTILE, GIOVANNI (1875–1944)

Best known as the self-styled philosopher of Fascism, Gentile, along with Benedetto Croce, was responsible for the ascendance of Hegelian idealism in Italy during the first half of the twentieth century. His 'actual' idealism or 'actualism' was a radical attempt to integrate our consciousness of experience with its creation in the 'pure act of thought', thereby abolishing the distinction between theory and practice. He held an extreme subjectivist version of idealism, and rejected both empirical and transcendental arguments as forms of 'realism' that posited the existence of a reality outside thought.

His thesis developed through a radicalization of Hegel's critique of Kant that drew on the work of the nineteenth-century Neapolitan Hegelian

Bertrando Spaventa. He argued that it represented both the natural conclusion of the whole tradition of Western philosophy, and had a basis in the concrete experience of each individual. He illustrated these arguments in detailed writings on the history of Italian philosophy and the philosophy of education respectively. He joined the Fascist Party in 1923 and thereafter placed his philosophy at the service of the regime. He contended that Fascism was best understood in terms of his reworking of the Hegelian idea of the ethical state, a view that occasionally proved useful for ideological purposes but which had little practical influence.

RICHARD BELLAMY

GERMAN IDEALISM

From the late eighteenth century until the middle of the nineteenth, German philosophy was dominated by the movement known as German idealism, which began as an attempt to complete Kant's revolutionary project: the derivation of the principles of knowledge and ethics from the spontaneity and autonomy of mind or spirit. However, German idealists produced systems whose relation to Kant is controversial, due to their emphasis on the absolute unity and historical development of reason.

As a movement to complete Kant's project, German idealism was punctuated by controversies about whether certain Kantian distinctions constitute *dualisms* – unbridgeable gaps between elements whose underlying unity must be demonstrated – and about how such dualisms can be overcome (see KANT, I. §3). One controversy concerned the distinction between the form of knowable objects – contributed by the mind, according to Kant – and the *matter* of sensation – contributed by mind-independent things-in-themselves. Jacobi objected that things-in-themselves lay beyond the boundaries of human knowledge, so Kant should profess 'transcendental ignorance' about the origin of sensible matter, leaving open the possibility that reality is mind-dependent. Another controversy concerned Kant's distinction between the spatio-temporal forms of sensibility and the categorial forms of understanding. Maimon argued that unless the underlying unity of this distinction were demonstrated, the applicability of categories to sensible objects could not be demonstrated against sceptics like HUME. Instead of defeating scepticism as he intended, some thought Kant had ensured its triumph by establishing unbridgeable dualisms between mind and reality, and between understanding and sensibility.

In the 1790s, some Kantians – notably REINHOLD, FICHTE and SCHELLING – sought to complete Kant's project through systematization. Troublesome dualisms would be overcome by positing distinct mental forms, as well as the distinction between mind and reality, as necessary conditions of the mind's free and unitary activity, and thus as necessary elements of a unified system. However, other Kantians – notably Buhle – accused the systematizers of undermining the distinctness of form and matter, and of attempting to generate matter from pure form. Meanwhile the systematizers, seeking to defeat scepticism, claimed metaphysical knowledge grounded in intellectual intuition of the mind's spontaneity. But Kant had explicitly denied that humans could attain such knowledge.

Professing continued allegiance to Kant despite these apparent departures, some systematizers – notably Fichte – claimed that Kant's teaching was only intelligible from a special standpoint and that, having attained that standpoint, they were expressing Kant's spirit, if not his letter. However, in his 1799 *Open Letter on Fichte's Wissenschaftslehre*, Kant publicly repudiated all attempts to discern his philosophy's spirit from a special standpoint and rejected any endeavour to bridge the gap between form and matter. But those who were repudiated did not change their ways. Finding Kant unable to complete the revolution he had started, they henceforth constructed their systems more independently of Kant's writings. The influence of pre-Kantian philosophers, notably SPINOZA, was explicitly acknowledged.

In order to overcome Kantian dualisms without ignoring his distinctions, Idealists produced a variety of developmental monisms (see FICHTE, J.G.; SCHELLING, F.W.J. VON; HEGEL, G.W.F. §4). Such systems portray a single, developing principle expressing itself in dualisms whose unstable, conflictual nature necessitates further developments. Thus reality is a developing, organic whole whose principle can be grasped and whose unity can be articulated in a philosophical system. But the dualisms encountered in everyday experience are not illusory. Rather, they are necessary stages in reality's development towards its full realization. This conception of development is often called dialectic.

Developmental monism emphasized the sociality and historicity of reason. Fichte was the first to emphasize sociality, arguing that the development of individual self-consciousness required consciousness of another mind, and deriving a theory of justice from the idea of one individual *recognizing* another as such. Hegel placed particular emphasis on historicity, portraying human history as a series of conflicts and resolutions culminating in a just society that would enable the reciprocal recognition

of individuals, as well as the perfect self-recognition of reason at which philosophy had always aimed (see Hegel, G.W.F. §8). Thus history – especially the history of philosophy – acquired unprecedented significance as the narrative of the mind's ascent to self-knowledge. And it was hoped that a philosophical account of society's historical development would correct the deficiencies of the French Revolution, which was often called the political equivalent of Kant's revolution.

Idealists disagreed about whether Kant's distinction between mind and nature was another problematic dualism. Schelling and Hegel argued that a systematic philosophy must portray nature as the mind's preconscious development. But Fichte regarded their philosophy of nature as a betrayal of Idealism that explained the mind in nonmental terms and deprived the mind of its autonomy. By 1801 the disagreement was explicit (see Fichte, J.G.; Schelling, F.W.J. von; Hegel, G.W.F. §§3, 7).

Controversy about another putative dualism – between concept and intuition – ended the alliance between Schelling and Hegel. Without naming him, Hegel's *Phenomenology of Spirit* (1807) appeared to criticize Schelling's view that philosophy can only be understood by those innately able to intuit – to grasp non-discursively – the identity implicit in apparent dualisms. Hegel argued that the completed philosophical system must be conceptualized and rendered discursively intelligible to everyone. However, only those who transformed their accustomed ways of thinking could understand the system (see Hegel, G.W.F. §§5, 6). So Hegel undertook to guide his readers through a series of transformations of consciousness representing the history of human thought, as well as the education of the individual. The Napoleonic wars forced Hegel from university life, but after his return in 1814, and especially after his move to Berlin in 1818, his version of idealism – with its portrayal of reason developing in both nature and culture towards conceptual articulation – became dominant.

However, Hegel died in 1831 and Schelling raised influential criticisms of Hegel when he began teaching in Berlin in 1841. In an inaugural lecture before an audience including Engels and Kierkegaard, Schelling argued that Hegel's system was an inevitably failed attempt to overcome the dualism between conceptual thought and intuited existence. Schelling's criticism was seminal for Marxism and existentialism and was more influential than his alternative proposals, which he had been developing under the influence of theosophy since 1809 (see Existentialism; Marxism, Western; Schelling, F.W.J. von; Hegelianism). The relationship between thought and existence remains problematic for post-idealist philosophy, and German idealism remains both an object of criticism and a source of insight.

PAUL FRANKS

GESTALT PSYCHOLOGY

The term 'Gestalt' was introduced into psychology by the Austrian philosopher Christian von Ehrenfels. 'Gestalt', in colloquial German, means 'shape' or 'structure'. Ehrenfels demonstrates in his essay of 1890 that there are certain inherently structural features of experience that must be acknowledged in addition to simple tones, colours and other mental 'atoms' or 'elements' if we are to do justice to the objects towards which perception, memory and abstract thinking are directed. His essay initiated a reaction against the then still dominant atomism in psychology, a reaction that led in turn to the ideas on 'cerebral integration' of the so-called Berlin school of Gestalt psychology and thence to contemporary investigations of 'neural networks' in cognitive science. Many of the specific empirical facts discovered by the Gestaltists about the perception of movement and contour, about perceptual constancy and perceptual illusions, and about the role of 'good form' in perception and memory have been absorbed into psychology as a whole.

BARRY SMITH

GETTIER PROBLEM

The emergence of the Gettier problem was an episode in the history of the project of trying to give necessary and sufficient conditions for knowledge. It was long supposed that knowledge could be defined

as justified true belief. But in 1963 Edmund Gettier published a very short paper arguing that this was not so: there can be cases of justified true belief which are not acceptable as cases of knowledge, hence the proposed conditions are not sufficient.

Gettier described two alleged counter-examples of this kind – cases of justified true belief which are not knowledge. But first he enunciated two general principles which quickly yield a recipe for generating such counter-examples:

1. In any sense of 'justified' in which being justified in believing that *p* can be thought a necessary condition of knowing that *p*, it is possible to be justified in believing a proposition which is, in fact, false.
2. For any proposition *p*, if a subject *S* is justified in believing *p*, and *p* entails *q*, and *S* deduces *q* from *p* and accepts *q* as a result of this deduction, then *S* is justified in believing *q*.

If these are accepted (and neither is easy to deny), we proceed as follows. Exploiting (1), imagine circumstances in which a person is justified in believing some proposition *p*, which is in fact false. Now suppose this person validly to deduce from *p* another proposition *q* and to believe *q* as a result of this deduction. (Make sure that *q* is weaker than *p*, that is *p* entails it but it does not entail *p*.) Finally, so adjust the story that *q* turns out to be true (so long as *q* is logically weaker than *p* this will always be possible). Then, by (2), *S*'s belief that *q* is a case of justified true belief. But surely *S* does not *know* that *q*? For so far as *S* is concerned the truth of *q* is wholly accidental: it is true not because of *p* – as *S* thought – but for some totally different reason of which *S* has no awareness.

Reactions have varied. Some have objected to the counter-examples themselves, others have accepted them and attempted to modify the definition of knowledge so as to avoid them. Others again have seen in them reason to rethink the whole project of defining knowledge in terms of necessary and sufficient conditions.

EDWARD CRAIG

AL-GHAZALI, ABU HAMID (1058–1111)

Al-Ghazali is one of the greatest Islamic jurists, theologians and mystical thinkers. He learned various branches of the traditional Islamic religious sciences in his home town of Tus, Gurgan and Nishapur in the northern part of Iran. He was also involved in Sufi practices from an early age. Being recognized by Nizam al-Mulk, the vizir of the Seljuq sultans, he was appointed head of the Nizamiyyah College at Baghdad in AH 484/AD 1091. As the intellectual head of the Islamic community, he was busy lecturing on Islamic jurisprudence at the College, and also refuting heresies and responding to questions from all segments of the community. Four years later, however, al-Ghazali fell into a serious spiritual crisis and finally left Baghdad, renouncing his career and the world. After wandering in Syria and Palestine for about two years and finishing the pilgrimage to Mecca, he returned to Tus, where he was engaged in writing, Sufi practices and teaching his disciples until his death. In the meantime he resumed teaching for a few years at the Nizamiyyah College in Nishapur.

Al-Ghazali explained in his autobiography why he renounced his brilliant career and turned to Sufism. It was, he says, due to his realization that there was no way to certain knowledge or the conviction of revelatory truth except through Sufism. (This means that the traditional form of Islamic faith was in a very critical condition at the time.) This realization is possibly related to his criticism of Islamic philosophy. In fact, his refutation of philosophy is not a mere criticism from a certain (orthodox) theological viewpoint. First of all, his attitude towards philosophy was ambivalent; it was both an object of criticism and an object of learning (for example, logic and the natural sciences). He mastered philosophy and then criticized it in order to Islamicize it. The importance of his criticism lies in his philosophical demonstration that the philosophers' metaphysical arguments cannot stand the test of reason. However, he was also forced to admit that the certainty of revelatory truth, for which he was so desperately searching, cannot be obtained by reason. It was only later that he finally attained to that truth in the ecstatic state (*fana'*) of the Sufi. Through his own religious experience, he worked to revive the faith of Islam by reconstructing the religious sciences upon the basis of Sufism, and to give a theoretical foundation to the latter under the influence of philosophy. Thus Sufism came to be generally recognized in the Islamic community. Though Islamic philosophy did not long survive al-Ghazali's criticism, he contributed greatly to the subsequent philosophization of Islamic theology and Sufism.

GLOBALIZATION

Globalization is one of the most hotly contested issues in contemporary social inquiry and public discussion. The debates mainly revolve around six points: definition, measurement, chronology, causes, consequences, and policy responses.

In regard to definition, five broad usages of 'globalization' can be distinguished: internationalization, liberalization, universalization, Westernization, and deterritorialization. Although these conceptions overlap to some extent, their emphases are substantially different.

With respect to magnitude, 'globalists' suggest that today's world is thoroughly globalized, whereas sceptics dismiss every claim of globalization as myth. Most observers agree that the incidence of globalization has been uneven, and that some countries and social circles have experienced globality more than others.

The chronology of globalization depends in good part on the definition adopted. Internationalization, liberalization, universalization and Westernization can all be traced back at least several centuries, if not millennia. On the other hand, deterritorialization has transpired on a large scale only since the third quarter of the twentieth century.

Accounts of the causal dynamics of globalization depend upon one's theoretical persuasion. However, most researchers explain globalization in some way as a product of modernity and/or capitalism. Many studies also highlight the enabling effects of certain technological developments and certain regulatory arrangements.

In terms of its consequences for social structure, some analysts treat globalization as radically transformative. Such accounts link globalization to the end of the state, the end of nationality, the end of modernity, and more. In contrast, other assessments downplay any suggestion of social change in connection with globalization. Still others conclude that globalization generates an interplay of changes and continuities in social structure.

Finally, in regard to policy, neoliberal approaches argue that globalization should be guided by market forces. In contrast, reformist strategies maintain that globalization should be deliberately steered with public policies, including in particular through suprastate laws and institutions. From a more radical position, traditionalists seek to ' de-globalize' and return to a pre-global *status quo ante*. Other radicals advocate a continuation of globalization, but in tandem with a revolutionary social transformation, for example, to a post-capitalist society.

JAN AART SCHOLTE

GNOSTICISM

Gnosticism comprises a loosely associated group of teachers, teachings and sects which professed to offer 'gnosis', saving knowledge or enlightenment, conveyed in various myths which sought to explain the origin of the world and of the human soul and the destiny of the latter. Everything originated from a transcendent spiritual power; but corruption set in and inferior powers emerged, resulting in the creation of the material world in which the human spirit is now imprisoned. Salvation is sought by cultivating the inner life while neglecting the body and social duties unconnected with the cult. The Gnostic movement emerged in the first and second centuries AD and was seen as a rival to orthodox Christianity, though in fact some Gnostic sects were more closely linked with Judaism or with Iranian religion. By the fourth century its influence was waning, but it persisted with sporadic revivals into the Middle Ages.

CHRISTOPHER STEAD

GOD, ARGUMENTS FOR THE EXISTENCE OF

Introduction

Arguments for the existence of God go back at least to Aristotle, who argued that there must be a first mover, itself unmoved. All the great medieval philosophers (Arabic and Jewish as well as Christian) proposed and developed theistic arguments – for example, Augustine, al-Ghazali, Anselm, Moses Maimonides, Thomas Aquinas and Duns Scotus. Most of the great modern philosophers – in particular René Descartes, Gottfried Leibniz and Immanuel Kant – have also offered theistic arguments. They remain a subject of considerable contemporary concern; the twentieth century has seen important work on all the main varieties of these arguments.

These arguments come in several varieties. Since Kant, the traditional Big Three have been the cosmological, ontological and teleological arguments. The cosmological argument goes back to Aristotle, but gets its classic statement (at least for European philosophy) in the famous 'five ways' of Aquinas, in particular his arguments for a first uncaused cause, a first unmoved mover, and a necessary being. According to the first-mover argument (which is a special case of the first-cause argument), whatever is moved (that is, caused to move) is moved by something else. It is impossible, however, that there should be an infinite series of

moved and moving beings; hence there must be a first unmoved mover. Aquinas goes on to argue that a first mover would have to be both a first cause and a necessary being; he then goes on in the next parts (Ia, qq.3–11) of the *Summa theologiae* to argue that such a being must have the attributes of God.

The perennially fascinating ontological argument, in Anselm's version, goes as follows: God is by definition the being than which none greater can be conceived. Now suppose God did not exist. It is greater to exist than not to exist; so if God did not exist, a being greater than God could be conceived. Since God is by definition the being than which none greater can be conceived, that is absurd. Therefore the supposition that God does not exist implies an absurdity and must be false. This argument has had many illustrious defenders and equally illustrious attackers from Anselm's time to ours; the twentieth century has seen the development of a new (modal) version of the argument.

Aquinas' fifth way is a version of the third kind of theistic argument, the teleological argument; but it was left to modern and contemporary philosophy to propose fuller and better-developed versions of it. Its basic idea is simple: the universe and many of its parts look as if they have been designed, and the only real candidate for the post of designer of the universe is God. Many take evolutionary theory to undercut this sort of argument by showing how all of this apparent design could have been the result of blind, mechanical forces. Supporters of the argument dispute this claim and retort that the enormously delicate 'fine tuning' of the cosmological constants required for the existence of life strongly suggests design.

In addition to the traditional Big Three, there are in fact many more theistic arguments. There are arguments from the nature of morality, from the nature of propositions, numbers and sets, from intentionality, from reference, simplicity, intuition and love, from colours and flavours, miracles, play and enjoyment, from beauty, and from the meaning of life; and there is even an argument from the existence of evil.

1 Cosmological arguments

Cosmological arguments start from some obvious and general but a posteriori fact about the universe: that there are contingent beings, for example, or that things move or change. We find first steps towards such an argument in Plato (*Laws* 10); ARISTOTLE (§16) (*Metaphysics* 12; *Physics* 7, 8) gives it a fuller statement; the medieval Arabic (especially AL-GHAZALI) and Jewish philosophers (especially Maimonides) gave elaborate statements of the argument; but its *locus classicus* (for Westerners, anyway) is the first three of the famous 'five ways' of Aquinas' *Summa theologiae*. Following Aquinas, DUNS SCOTUS presented a subtle and powerful version of the argument, and in modern times the most influential versions of the argument are to be found in the works of LEIBNIZ (§3) and Samuel CLARKE. (The most influential criticisms of the argument are given by HUME (§6) and KANT (§8).)

Following William Craig (1980), we may distinguish substantially three versions of the cosmological argument. First, the so-called *kalam* (Arabic, 'speculative theology') argument, developed by Arabic thinkers (for example, al-Kindi and al-Ghazali). Put most schematically, this argument goes as follows:

(1) Whatever begins to exist is caused to exist by something else.
(2) The universe began to exist.
(3) Therefore the universe was caused to exist; and the cause of its existence is God.

The second premise was supported by arguments for the conclusion that an 'actual infinite' is not possible: it is not possible, for example, that there have been infinitely many temporally non-overlapping beings each existing for at least a second; alternatively, it is not possible that an infinite number of seconds have elapsed. These arguments proceed by pointing out some of the paradoxes or peculiarities that an actual infinite involves (see INFINITY). For example, suppose there were a hotel with infinitely many rooms ('Hilbert's Hotel'). The hotel is full; a new guest arrives; despite the fact that each room is already occupied, the proprietor accommodates the guest by putting them in room 1, moving the occupant of room 1 to room 2, of room 2 to room 3, and in general the occupant of n to n+1. No problem! Indeed, when a large bus containing infinitely many new guests pulls up, they too can all be accommodated: for any odd-numbered room n, move its occupant into room 2n (moving the occupant of *that* room n* into 2n*, and so on), thus freeing up the infinitely many odd-numbered rooms. In fact, if it is a busy weekend and an infinite fleet of buses pulls up, each with infinitely many new guests, they too can all be easily accommodated. And the question is: is it really possible, in the broadly logical sense, that such a hotel could actually exist? The friend of the *kalam* argument thinks not, and adds that no other actual infinite is possible either. If so, then the universe has

not existed for an infinite stretch of time, but had a beginning. Contemporary cosmological theory in physics has seemed to some to provide scientific, empirical support for the claim that the universe had a beginning; according to 'Big Bang' cosmology, the universe came into being something like 15 billion years ago, give or take a few billion (see COSMOLOGY).

Given that the universe has a beginning, the next step is to argue (by way of the first premise) that it must therefore have had a cause; it could not have popped into existence uncaused. And the final step is to argue that the cause of the universe would have to have certain important properties – properties of God.

The second kind of cosmological argument is the kind to be found in the first three of Aquinas' five ways. His second way, for example, goes like this:

(1) Many things in nature are caused.
(2) Nothing is a cause of itself.
(3) An infinite regress of essentially ordered efficient causes is impossible.
(4) Therefore, there is a first uncaused cause – 'to which', says Aquinas, 'everyone gives the name of God'.

There are two points of particular interest about this argument. First, Aquinas disagrees with a premise of the *kalam* argument, according to which it is impossible that there be an actual infinite. He argues that it cannot be proved that the universe had a beginning; he thinks it possible (though false) that the universe has existed for an infinite stretch of time. How then are we to understand premise (3)? Aquinas is here speaking of a certain kind of series, an 'essentially ordered' series, a series of causes in which any cause of an effect must be operating throughout the whole duration of the effect's operation. It is only such series, he says, that cannot proceed to infinity. (Aquinas gives the example of a stick moving a stone, a hand moving the stick, and so on.) So the upshot of the argument, if it is successful, is that there exists at least one thing which causes other things to exist, but is not itself caused to exist by anything else.

But could there not be many such things? And would each of them be God? This brings us to the second point of interest. Aquinas argues that there must be a first unmoved mover, a first uncaused cause, a necessary being, and the like; but his theistic argument is not finished there. In the next eight questions he argues that anything that was a first efficient cause would have to be immaterial, unchanging, eternal, simple and the possessor of all the perfections to be found in those things dependent upon it – in a word, God. It is therefore incorrect to follow the usual custom of criticizing Aquinas for hastily concluding that a first cause or unmoved mover or necessary being would have to be God.

The third sort of cosmological argument is associated especially with Leibniz and Samuel Clarke; according to this version of the argument, there must be a sufficient reason for the actuality of any contingent state of affairs. Therefore there must be a sufficient reason for the existence of any contingent being – but also, says Leibniz, for the whole series of contingent beings. This sufficient reason must be the activity of God.

2 Ontological arguments

Anselm's ontological argument has excited enormous controversy (see ANSELM OF CANTERBURY). Aquinas rejected it, Duns Scotus 'coloured' it a bit and then accepted it; DESCARTES (§6) and MALEBRANCHE endorsed it; like Duns Scotus, Leibniz thought it needed just a bit of work to be successful; Kant rejected it and delivered what many thought to be the final quietus (though others have found Kant's criticisms both intrinsically obscure and of doubtful relevance to the argument); and Schopenhauer thought it a 'charming joke'. Although in the twentieth century it was defended by (among others) Charles Hartshorne, Norman Malcolm and Alvin Plantinga, probably most contemporary philosophers reject the argument, thinking it a joke, but not particularly charming.

Anselm's version goes as follows:

> Hence, even the fool is convinced that something exists in the understanding, at least, than which nothing greater can be conceived.... And assuredly that, than which nothing greater can be conceived, cannot exist in the understanding alone; for suppose it exists in the understanding alone; then it can be conceived to exist in reality; which is greater.
>
> Therefore, if that, than which nothing greater can be conceived, exists in the understanding alone, the very being, than which nothing greater can be conceived is one, than which a greater can be conceived. But obviously this is impossible. Hence, there is no doubt that there exists a being, than which nothing greater can be conceived, and it exists both in the understanding and in reality.
>
> (*Proslogion*, ch. 2)

This argument is a *reductio ad absurdum*: postulate the nonexistence of God, and show that this leads to an absurdity. Perhaps we can outline the argument as follows:

(1) A maximally great being (one than which nothing greater can be conceived) exists in the understanding (that is, is such that we can conceive of it).
(2) It is greater to exist in reality than to exist merely in the understanding.
(3) Therefore, if the maximally great being existed *only* in the understanding, it would be less than maximally great.

But it is impossible that the maximally great being be less than maximally great; hence this being exists in reality as well as in the understanding – that is, it exists. And clearly this maximally great being is God.

The earliest objection to this argument was proposed by Anselm's contemporary and fellow monk Gaunilo in his *On Behalf of the Fool* (Psalm 14: 'The fool has said in his heart "There is no God"'). According to Gaunilo, the argument must be defective, because we can use an argument of the very same form to demonstrate the existence of such absurdities as an island (or chocolate sundae, or hamster, for that matter) than which none greater can be conceived. (Says Gaunilo: 'I know not which I ought to regard as the greater fool: myself, supposing that I should allow this proof; or him, if he should suppose that he had established with any certainty the existence of this island.') But Anselm has a reply: the notion of a maximally great island, like that of a largest integer, does not make sense, cannot be exemplified. The reason is that the properties that make for greatness in an island – size, number of palm trees, quality of coconuts – do not have intrinsic maxima; for any island, no matter how large and no matter how many palm trees, it is possible that there be one even larger and with more palm trees. But the properties that make for greatness in a being – knowledge, power and goodness, for example – do have intrinsic maxima: omniscience, omnipotence and being perfectly good.

3 Ontological arguments (cont.)

The most celebrated criticism of the ontological argument comes from Immanuel Kant, who apparently argues in his *Critique of Pure Reason* (Transcendental Dialectic, bk II, ch. III, section 4) that if this argument were sound, the proposition 'there is a being than which none greater can be conceived' would have to be logically necessary; but there cannot be an existential proposition that is logically necessary. Sadly, his reason for making this declaration is itself maximally obscure. He adds that 'existence is not a real predicate', which is widely quoted as the principal objection to the argument. Unfortunately this dictum is of dubious relevance to Anselm's argument and a dark saying in its own right. What might it mean to say that existence is not a real property or predicate? And if it is not, how is that relevant to the argument? Why should Anselm care whether it is or not?

Perhaps we can understand Kant as follows. The argument as stated begins with the assertion that a maximally great being exists in the understanding; the idea is that this much is obvious, whether or not this being also exists in reality (that is, actually exists). Anselm then goes on to reason about this being, arguing that a being with the properties this one has – of being maximally great – cannot exist only in the understanding, but must exist in reality as well. So the argument depends upon the assumption that there *is* a maximally great being, and now the question is: does this being actually exist? Use the term 'actualism' for the view that there are not (and could not be) things that do not exist; the things that exist are all the things there are. Note that if this is true, then existence is a very special property: it is redundant, in that it is implied by every other property; anything that has *any* property (including the property of being maximally great) also has existence. But if actualism is true, the ontological argument as formulated above cannot work. For if it is not possible that there be things that do not exist, then in saying initially that there is a maximally great being, one that at any rate exists in the understanding, we are already saying that there exists a maximally great being, thus begging the question. If no maximally great being exists, then there simply is no such thing as a maximally great being, in which case we cannot (following Anselm) suppose initially that the maximally great being does not exist in reality and then argue that this being would be greater if it did exist in reality. If actualism is true, existence is a redundant property; but then to say that there is a maximally great being that exists in the understanding is already to say that there really exists a maximally great being. So perhaps Kant's puzzling dictum should be seen as an early endorsement of actualism.

Of course Anselm might reply that the fault lies not with his argument, but with actualism; in any event, there are other versions that do not conflict with actualism. Charles Hartshorne claimed to detect two quite different versions of the argument in Anselm's work; the second version is consistent with actualism and thus sidesteps Kant's criticism. This version proceeds from the thought that a really great being would be one that would have been great even if things had been different; its greatness is stable across possible worlds, to put it in a misleading if picturesque way. So say that a being has *maximal excellence* in a given possible world W if

and only if it is omnipotent, omniscient and wholly good in *W*; and say that a being has *maximal greatness* if it has maximal excellence in every possible world. Then the premise of the argument (thus restated) is simply:

> Maximal greatness is possibly exemplified.

That is, it is possible that there be a being that has maximal greatness. But (given the widely accepted view that if a proposition is possibly necessary in the broadly logical sense, then it is necessary), it follows by ordinary modal logic that maximal greatness is not just possibly exemplified, but exemplified in fact. For maximal greatness is exemplified if and only if there is a being *B* such that the proposition

> *B* is omnipotent and omniscient and wholly good (has maximal excellence)

is necessary. If maximal greatness is possibly exemplified, therefore, then some proposition of that sort is possibly necessary. By the above principle, whatever is possibly necessary is necessary; accordingly, that proposition is necessarily true and hence true.

So stated, the ontological argument breaches no laws of logic, commits no confusions and is entirely immune to Kant's criticism. The only remaining question of interest is whether its premise, that maximal greatness is possibly exemplified, is indeed true. That certainly seems to be a rational claim; but it is not one that cannot rationally be denied. A remaining problem with the argument, perhaps, is that it might be thought that the epistemic distance between premise and conclusion is insufficiently great. Once you see how the argument works, you may think that asserting or believing the premise is tantamount to asserting or believing the conclusion; the canny atheist will say that he does not believe it is possible that there be a maximally great being. But would not a similar criticism hold of any valid argument? Take any valid argument: once you see how it works, you may think that asserting or believing the premise is tantamount to asserting or believing the conclusion. The ontological argument remains as intriguing as ever.

4 Teleological arguments

Teleological arguments start from contingent premises that involve more specific features of the universe, features which in one way or another suggest that the universe has been designed by a conscious and intelligent being. These arguments have often been developed in close connection with modern science; they have been endorsed by many of the giants of modern science, including Isaac Newton. Here is a classic statement of the argument by William PALEY:

> In crossing a heath, suppose I pitched my foot against a *stone*, and were asked how the stone came to be there, I might possibly answer that for any thing I know to the contrary, it had lain there for ever: nor would it perhaps be very easy to show the absurdity of this answer. But suppose I had found a *watch* upon the ground and it should be inquired how the watch happened to be in that place, I should hardly think of the answer which I had before given, that, for any thing I know the watch might have always been there. Yet why should not this answer serve for the watch, as well as for the stone? For this reason and for no other: viz., that, when we come to inspect the watch, we perceive (what we could not discover in the stone) that its several parts are framed and put together for a purpose.
>
> (*Natural Theology* 1802)

Paley then points out that the universe and some of its parts – for example, living things and their organs – resemble a watch, in that they give the appearance of having been designed in order to accomplish certain purposes. An eye, for example, looks like an extremely subtle and sophisticated mechanism designed to enable its owner to see. But the only serious candidate for the post of designer of the universe is God.

Kant, who had little but contempt for the cosmological and ontological arguments, was much less dismissive of this one. He still rejected the argument, however, pointing out that at most it shows that it is likely that there is a designer or architect of the universe; and it is a long way from a designer to the God of the theistic religions, an almighty, omniscient, wholly good creator of the world, by whose power the universe sprang into being. Of course, a cosmic architect – a being who has designed our entire universe, with its elements ranging across many orders of magnitude from gigantic galaxies to the minutest things we know – is no mean conclusion, and it seems churlish to dismiss it with an airy wave in order to point out that there is something even stronger that the teleological argument does not show.

5 Teleological arguments (cont.)

Many people, however, have rejected the teleological argument even taken as an argument for a designer. The eighteenth-century proponents of the argument invariably mentioned the apparent teleology in the biological world; but (so say the critics) Darwin changed all that. We now know that the

apparent design in the world of living things is *merely* apparent. The enormous variety of flora and fauna, those enormously elaborate and articulate mechanisms and finely detailed systems and organs such as the mammalian eye and the human brain give a powerful impression of design; but in fact they are the product of such blind mechanisms as random genetic mutation and natural selection. The idea is that there is a source of genetic variation which produces mutation in the structure and function of existing organisms. Most of these mutations are deleterious; a few are adaptive and their lucky owners will have an adaptive edge, eventually coming to predominate in a population. Given enough time, so the story goes, this process can produce all the splendid complexity and detail that characterize the contemporary living world (see Evolution, theory of).

Of course there is little real evidence that these processes can in fact achieve this much: naturally enough, we have not been able to follow their operation in such a way as to observe them produce, say, birds or mammals from reptiles, or even human beings from simian precursors. And even if we did observe the course of animate history (even if we had a detailed record on film), this would by no means show that blind mechanisms are in fact sufficient for this effect; for of course there would be nothing in the film record to show that those random genetic mutations were not in fact guided and orchestrated by God.

Still, the critic of the teleological argument claims not that in fact evolution has been accomplished just by these blind mechanisms, but that it could have been; if so, there is a real alternative to design. That these mechanisms really could have produced effects of this magnitude is far from clear; we have little real reason to suppose that there is a path through the space of possible animal design plans, a path leading from bacteria to human beings, and such that each new step is both adaptive and reachable from the previous step by mechanisms we understand. Still, the suggestion does perhaps damage the teleological argument by suggesting a naturalistic candidate for the post of producer of apparent design.

But organic evolution addresses only one of the areas of apparent design. There is also the origin of life; even the simplest unicellular creatures (prokaryotes such as bacteria and certain algae, for example) are enormously complex and upon close inspection look for all the world as if they have been designed; it is fair to say that no one, so far, has a decent idea as to how these creatures might have come into being just by way of the operation of the regularities of physics and chemistry. There are also the various considerations connected with the so-called 'fine tuning' of the universe. First, there is the 'flatness' problem. The mass density of the universe is at present very close to the density corresponding to the borderline between an open universe (one that goes on expanding for ever) and a closed universe (one that expands to a certain size and then collapses). The ratio between the forces making for expansion and those making for contraction is close to one. But then shortly after the Big Bang this value would have to have been inside a very narrow band indeed. Thus Stephen Hawking, in his 'The Antisotropy of the Universe at Large Times' (1974): 'reduction of the rate of expansion by one part in 10^{12} at the time when the temperature of the Universe was 10^{10} K would have resulted in the Universe's starting to recollapse when its radius was only 1/3000 of the present value and the temperature was still 10,000 K' – much too warm for the development of life. On the other hand, if the rate of expansion had been even minutely greater, the universe would have expanded much too fast for the formation of stars and galaxies, required for the formation of the heavy elements necessary for the development of life.

Another kind of fine tuning was also necessary: of the fundamental physical constants. If any of the four fundamental forces (weak and strong nuclear forces, electromagnetic force, electron charge) had been even minutely different, the universe would not have supported life; they too must have been fine-tuned to an almost unbelievable accuracy. And the suggestion, again, is that given the infinite range of possible values for the fundamental constants, design is suggested by the fact that the actual values fall in that extremely narrow range of values that permits the development of intelligent life.

But there is a naturalistic riposte. Since the 1970s, several different sorts of 'inflationary' scenario have shown up. These postulate the formation (at very early times) of many different universes or subuniverses, with different rates of expansion, and different values for the fundamental constants. These inflationary models are motivated, in part, by a desire to avoid singularities and the accompanying appearance of design. If all possible values for the fundamental constants and the rate of expansion are actually exemplified in different subuniverses, then the fact that there is a subuniverse with the values ours displays no longer requires explanation or suggests a Designer. Many of these scenarios are wildly speculative and unencumbered by empirical evidence, but (if physically acceptable) they do tend to blunt the force of a design argument from fine tuning. (Of course, someone who already believed in God and saw no need to eliminate suggestions of design might be inclined to reject these suggestions as

metaphysically extravagant.) But there are also counterarguments here; the discussion goes on. It is hard to see a verdict, at present, on the prospects of this form of the argument. The teleological argument seems to have enormous vitality; its epitaph is often read, but the argument regularly reappears in new forms. As for a final evaluation, the best perhaps comes from Kant, who said that this argument 'always deserves to be mentioned with respect. It is the oldest, the clearest and the most accordant with the common reason of mankind' (*Critique of Pure Reason*).

6 Other theistic arguments

We have examined the Big Three among theistic arguments, but there are many more. First, there are moral arguments of at least two sorts. These are arguments that the very nature of morality – the unconditioned character of the moral law – requires a divine lawgiver. You might find yourself utterly convinced that:

> Morality is objective, not dependent upon what human beings know or think or do.

You may also be convinced that:

> The objective character of morality cannot be explained in terms of any 'natural' facts about human beings (or other things), so there could not be such a thing as objective moral law unless there were a being like God who legislates it.

Then you will have a theistic argument from the nature of morality. This argument can go in either of two directions: some people think we can simply *see* that moral obligation is impossible apart from a divine will and lawgiver, while others think that the dependence of moral obligation upon the will of God is the best explanation for its objectivity and special deontological force.

A second main type of moral argument is due to Kant, who argues first that virtue deserves to be proportionally rewarded with happiness: the more virtuous you are, the more happiness you deserve. But nature by itself does not seem able to guarantee anything like this sort of coincidence. If morality is to make sense, however, it must be supposed that there is such a coincidence; practical reason, therefore, is entitled to postulate a supernatural being with enough knowledge, power and goodness to ensure that we receive the happiness we deserve as a reward for our virtue. So taken, the argument is for the rationality of making the assumption that there is a being of this sort; it is not really an argument for the actual existence of such a being. This argument receives criticism from several sides: some hold that we do not have to assume that there is proportionality between virtue and happiness in order to carry out the moral life; others (for example, many Christians) argue that both happiness and the ability to live a moral life are gifts of grace and that if we really got what we deserve, we should all be thoroughly miserable.

There are many other theistic arguments – arguments from the nature of proper function, from the nature of propositions, numbers and sets, from intentionality, from counterfactuals, from the confluence of epistemic reliability with epistemic justification, from reference, simplicity, intuition, love, colours and flavours, miracles, play and enjoyment, morality, beauty, the meaning of life, and even from the existence of evil. There is no space even to outline all these arguments, so we will look at just three.

First, the argument from intentionality (or aboutness). Consider propositions – the things that are true or false, that are capable of being believed, and that stand in logical relations to one another. Propositions have another property: *aboutness* or *intentionality.* They represent reality or some part of it as being thus and so, and it is by virtue of this property that propositions (as opposed, for example, to sets) are true or false. Most who have thought about the matter have found it incredible that propositions should exist apart from the activity of minds. How could they just *be* there, if never thought of? Further, representing things as being thus and so – being about something or other – seems to be a property or activity of minds or perhaps thoughts. It is therefore extremely plausible to think of propositions as ontologically dependent upon mental or intellectual activity in such a way that either they just *are* thoughts, or else at any rate could not exist if not thought of. But propositions cannot be human thoughts; there are far too many of them for that. (For each real number *r*, for example, there is the proposition that *r* is distinct from the Taj Mahal.) Hence the only viable possibility is that they are divine thoughts, God's thoughts (so that when we think, we literally think God's thoughts after him).

Second, there is the argument from sets or collections. Many think of sets as displaying the following characteristics: (1) no set is a member of itself; (2) sets (unlike properties) have their extensions essentially – hence many sets are contingent beings and no set could have existed if one of its members had not; (3) sets form an iterated structure – at the first level, there are sets whose members are nonsets, at the second, sets whose members are nonsets or first level sets, . . . , at the

*n*th level, sets whose members are nonsets or sets of index less than *n*, . . . , and so on.

It is also natural to follow Georg Cantor, the father of modern set theory, in thinking of sets as collections – that is, as things whose existence depends upon a certain sort of intellectual activity, a collecting or 'thinking together' as Cantor put it. If sets were collections, that would explain their having the first three features. But of course there are far too many sets for them to be a product of human thinking together; there are many sets such that no human being has ever thought their members together and many such that no human being *could* think them together. That requires an infinite mind – one such as God's.

For a third example, consider the argument from appalling evil. Many philosophers offer antitheistic arguments from evil, and perhaps they have some force. But there is also a *theistic* argument from evil. The premise is that there is real and objectively horrifying evil in the world. Examples would be certain sorts of appalling evil characteristic of Nazi concentration camps: guards found pleasure in devising tortures, making mothers decide which of their children would go to the gas chamber and which be spared; small children were hanged, dying (because of their light weight) a slow and agonizing death; victims were taunted with the claim that no one would ever know of their fate and how they were treated. Of course, Nazi concentration camps have no monopoly on this sort of evil: there are also Stalin, Pol Pot and a thousand lesser villains. These states of affairs, one thinks, are objectively horrifying, in the sense that they would constitute enormous evil even if we and everyone else came perversely to approve of them.

Naturalism does not have the resources to accommodate or explain this fact about these states of affairs. From a naturalistic point of view, about all one can say is that we do indeed hate them; but this is far short of seeing them as intrinsically horrifying. How can we understand this intrinsically horrifying character? After all, as much misery and suffering can occur in a death from cancer as in a death caused by someone else's wickedness. What is the difference? The difference lies in the perpetrators and their intentions. Those who engage in this sort of evil are purposely and intentionally setting themselves to do these wicked things. But why is that objectively horrifying? A good answer (and one for which it is hard to think of an alternative) is that this evil consists in defying God, the source of all that is good and just, and the first being of the universe. What is horrifying here is not merely going contrary to God's will, but consciously choosing to invert the true scale of values, explicitly aiming at what is abhorrent to God. This is an offence and affront to God; it is defiance of God himself, and so is objectively horrifying. Appalling evil thus has a sort of cosmic significance. But of course there could be no evil of this sort if there were no such being as God.

GOD, CONCEPTS OF

We think of God as an ultimate reality, the source or ground of all else, perfect and deserving of worship. Such a conception is common to both Eastern and Western religions. Some trace this to human psychology or sociology: Freud regarded God as a wish-fulfilling projection of a perfect, comforting father-figure; Marxists see belief in God as arising from the capitalist structure of society. Believers, however, trace their belief to religious experience, revealed or authoritative texts, and rational reflection.

Philosophers flesh out the concept of God by drawing inferences from God's relation to the universe ('first-cause theology') and from the claim that God is a perfect being. 'Perfect-being' theology is the more fundamental method. Its history stretches from Plato and Aristotle, through the Stoics, and into the Christian tradition as early as Augustine and Boethius; it plays an important role in underwriting such ontological arguments for God's existence as those of Anselm and Descartes. It draws on four root intuitions: that to be perfect is perfectly to be, that it includes being complete, that it includes being all-inclusive, and that it includes being personal. Variously balanced, these intuitions yield our varied concepts of God.

Criticisms of perfect-being theology have focused both on the possibility that the set of candidate divine perfections may not be consistent or unique,

and doubts as to whether human judgment can be adequate for forming concepts of God. Another problem with the method is that different accounts of perfection will yield different accounts of God: Ibn Sina and Ibn Rushd, for instance, appear to have held that God would be the more perfect for lacking some knowledge, while most Christian writers hold that perfection requires omniscience.

Views of God's relation to the universe vary greatly. Pantheists say that God *is* the universe. Panentheists assert that God includes the universe, or is related to it as soul to body. They ascribe to God the limitations associated with being a person – such as limited power and knowledge – but argue that being a person is nevertheless a state of perfection. Other philosophers, however, assert that God is wholly different from the universe.

Some of these think that God created the universe *ex nihilo*, that is, from no pre-existing material. Some add that God conserves the universe in being moment by moment, and is thus provident for his creatures. Still others think that God 'found' some pre-existing material and 'creates' by gradually improving this material – this view goes back to the myth of the Demiurge in Plato's *Timaeus*, and also entails that God is provident. By contrast, deists deny providence and think that once God made it, the universe ran on its own. Still others argue that God neither is nor has been involved in the world. The common thread lies in the concept of perfection: thinkers relate God to the universe in the way that their thoughts about God's perfection make most appropriate.

BRIAN LEFTOW

GÖDEL'S THEOREMS

Utilizing the formalization of mathematics and logic found in Whitehead and Russell's *Principia Mathematica* (1910), Hilbert and Ackermann gave precise formulations of a variety of foundational and methodological problems, among them the so-called 'completeness problem' for formal axiomatic theories – the problem of whether all truths or laws pertaining to their subjects are provable within them. Applied to a proposed system for first-order quantificational logic, the completeness problem is the problem of whether all logically valid formulas are provable in it.

In his doctoral dissertation of 1929, Gödel gave a positive solution to the completeness problem for a system of quantificational logic based on the work of Whitehead and Russell. This is the first of the three theorems that we here refer to as 'Gödel's theorems'.

The other two theorems arose from Gödel's continued investigation of the completeness problem for more comprehensive formal systems – including, especially, systems comprehensive enough to encompass all known methods of mathematical proof. Here, however, the question was not whether all logically valid formulas are provable (they are), but whether all formulas true in the intended interpretations of the systems are.

For this to be the case, the systems would have to prove either S or the denial of S for each sentence S of their languages. In his first incompleteness theorem, Gödel showed that the systems investigated were not complete in this sense. Indeed, there are even sentences of a simple arithmetic type that the systems can neither prove nor refute, provided they are consistent. So even the class of simple arithmetic truths is not formally axiomatizable.

The idea behind Gödel's proof is basically as follows. Let a given system T satisfy the following conditions: (1) it is powerful enough to prove of each sentence in its language that if it proves it, then it proves that it proves it, and (2) it is capable of proving of a certain sentence G (Gödel's self-referential sentence) that it is equivalent to 'G is not provable in T'. Under these conditions, T cannot prove G, so long as T is consistent. For suppose T proved G. By (1) it would also prove 'G is provable in T', and by (2) it would prove 'G is not provable in T'. Hence, T would be inconsistent.

Under slightly stronger conditions – specifically, (2) and (1′) every sentence of the form 'X is provable in T' that T proves is true – it can be shown that a consistent T cannot prove 'not G' either. For if 'not G' were provable in T it would follow by (2) that 'G is provable in T' would also be provable in T. But then by (1′) G would be provable. Hence, T would be inconsistent.

The proof of Gödel's second incompleteness theorem essentially involves formalizing in T a proof of a formula expressing the proposition that if T is consistent, then G. The second incompleteness theorem (that is, the claim that if T is consistent it cannot prove its own consistency) then follows from this and the first part of the proof of the first incompleteness theorem.

The two incompleteness theorems have been applied to a wide variety of concerns in philosophy. The best known of these are critical applications to Hilbert's programme and logicism in the philosophy of mathematics and to mechanism in the philosophy of mind.

MICHAEL DETLEFSEN

GOETHE, JOHANN WOLFGANG VON (1749–1832)

Goethe was a statesman, scientist, amateur artist, theatrical impresario, dramatist, novelist and Germany's supreme lyric poet; indeed he provided the Romantic generation which followed him with their conception of what a poet should be. His works, diaries and about 12,000 letters run to nearly 150 volumes. His drama *Faust* (1790–1832) is the greatest long poem in modern European literature and made the legend of Dr Faust a modern myth. He knew most of the significant figures in the philosophical movement of German idealism (though he never met Kant), but he was not himself a philosopher. His literary works certainly addressed contemporary philosophical concerns: *Iphigenie auf Tauris* (Iphigenia in Tauris) (1779–86) seems a prophetic dramatization of the ethical and religious autonomy Kant was to proclaim from 1785; in his novel *Die Wahlverwandtschaften* (The Elective Affinities) (1809) a mysterious natural or supernatural world of chemistry, magnetism or Fate, such as '*Naturphilosophie*' envisaged, seems to underlie and perhaps determine a human story of spiritual adultery; in *Faust*, particularly *Part Two*, the tale of a pact or wager with the Devil seems to develop into a survey of world cultural history, which has been held to have overtones of Schelling, Hegel or even Marx. But whatever their conceptual materials, Goethe's literary works require literary rather than philosophical analysis. There are, however, certain discrete concepts prominent in his scientific work, or in the expressions of his 'wisdom' – maxims, essays, autobiographies, letters and conversations – with which Goethe's name is particularly associated and which are capable of being discussed separately. Notable among these are: Nature and metamorphosis (*Bildung*), polarity and 'intensification' (*Steigerung*), the 'primal phenomena' (*Urphänomene*), 'the daemonic' (*das Dämonische*) and renunciation (*Entsagung*).

GOOD AND RIGHT

See Right and good

GOOD, THEORIES OF THE

'Good' is the most general term of positive evaluation, used to recommend or express approval in a wide range of contexts. It indicates that a thing is desirable or worthy of choice, so that normally, if you have reason to want a certain kind of thing, you also have reason to prefer a *good* thing of that kind.

A theory of the good may consist in a general account of the good, which is meant to apply to all good things; or in a definition of 'good', an account of how the term functions in the language. Theories of the good have metaphysical implications about the relations of fact and value. Many ancient and medieval philosophers believed in the ultimate identity of the real and the good. Modern philosophers reject this identification, and have held a range of positions: realists, for example, hold that the good is part of reality, while certain moral sense theorists hold that when we call something good we are projecting human interests onto reality; and emotivists hold that we use the term 'good' only to signify subjective approval.

Theorists of the good also categorize different kinds of goodness and explain how they are related. Good things are standardly classified as ends, which are valued for their own sakes, or means, valued for the sake of the ends they promote. Some philosophers also divide them into intrinsic goods, which have their value in themselves, and extrinsic goods, which get their value from their relation to something else. Various theories have been held about the relation between these two distinctions – about whether an end must be something with intrinsic value. Philosophers also distinguish subjective goods – things which are good for someone in particular – from objective goods, which are good from everyone's point of view. Views about how these kinds of goodness are related have important implications for moral philosophy.

Usually, a theory of the good is constructed in the hope of shedding light on more substantive questions, such as what makes a person, an action, or a human life good. These questions raise issues about the relation between ethical and other values. For example, we may ask whether moral virtue is a special sort of goodness, or just the ordinary sort applied to persons. Or, since actions are valued as 'right' or 'wrong', we may ask how these values are related to the action's goodness or badness. We may also pose the question of whether a life that is good in the sense of being *happy* must also be a *morally good* or virtuous life. This last question has occupied the attention of philosophers ever since Plato.

CHRISTINE M. KORSGAARD

GORGIAS (late 5th Century BC)

The most important of the fifth-century BC Greek Sophists after Protagoras, Gorgias was a famous rhetorician, a major influence on the development of artistic prose and a gifted dabbler in philosophy. His display speeches, *Encomium of Helen of Troy* and *Defence of Palamedes*, are masterpieces of the art of making a weak case seem strong, and brilliant exercises in symmetrical and antithetical sentence structure. Of philosophical importance is his treatise *On Not-Being, or On the Nature of Things*, an elaborate reversal of the metaphysical argument of Parmenides, showing: (1) that nothing exists; (2) that if anything exists, it cannot be known; and (3) if anything can be known, it cannot be communicated. This nihilistic *tour de force* is probably a caricature rather than a serious statement of a philosophical position. Gorgias is a master of the persuasive use of *logos* (discourse), understood both as eloquence and as argumentative skill.

GREEN POLITICAL PHILOSOPHY

All the major political philosophies have been born of crisis. Green political philosophy is no exception to this general rule. It has emerged from that interconnected series of crises that is often termed 'the environmental crisis'. As we enter the third millennium and the twenty-first century it seems quite clear that the level and degree of environmental degradation and destruction cannot be sustained over the longer term without dire consequences for human and other animal species, and the ecosystems on which all depend. A veritable explosion in the human population, the pollution of air and water, the over-fishing of the oceans, the destruction of tropical and temperate rain forests, the extinction of entire species, the depletion of the ozone layer, the build-up of greenhouse gases, global warming, desertification, wind and water erosion of precious topsoil, the disappearance of valuable farmland and wilderness for 'development' – these and many other interrelated phenomena provide the backdrop and justification for the 'greening' of much of modern political thinking.

The task of outlining and summarizing the state of green political philosophy is made more difficult because there is as yet no agreement among 'green' political thinkers. Indeed there is, at present, no definitive 'green political philosophy' as such. The environmental or green movement is diverse and disparate, and appears in different shades of green. These range from 'light green' conservationists to 'dark green' deep ecologists, from ecofeminists to social ecologists, from the militant ecoteurs of Earth First! to the low-keyed gradualists of the Sierra Club and the Nature Conservancy. These groups differ not only over strategy and tactics, but also over fundamental philosophy.

While there is no single, systematically articulated and agreed-upon green political philosophy, however, there are none the less recurring topics, themes, categories and concepts that are surely central to such a political philosophy. These include the idea that humans are part of nature and members of a larger and more inclusive 'biotic community' to which they have obligations or duties. This community includes both human and non-human animals, and the conditions conducive to their survival and flourishing. Such a community consists, moreover, not only of members who are alive but those who are as yet unborn. A green political philosophy values both biological and cultural diversity, and views sustainability as a standard by which to judge the justness of human actions and practices. Exactly how these themes might fit together to form some larger, systematic and coherent whole is still being worked out.

TERENCE BALL

GREEN, THOMAS HILL (1836–82)

Green was a prominent Oxford idealist philosopher, who criticized both the epistemological and ethical implications of the dominant empiricist and utilitarian theories of the time. He contended that experience could not be explained merely as the product of sensations acting on the human mind. Like Kant, Green argued that knowledge presupposes certain a priori categories, such as substance, causation, space and time, which enable us to structure our understanding of empirical reality. Physical objects and even the most simple feelings are only intelligible as relations of ideas constituted by human consciousness. However, unlike Kant, he did not draw the conclusion that things in themselves are consequently unknowable. Rather, he argued that reality itself is ultimately spiritual, the product of an eternal consciousness operating within both the world and human reason. Green

adopted a similarly anti-naturalist and holistic position in ethics, in which desires are seen as orientated towards the realization of the good – both within the individual and in society at large. In politics, this led him to criticize the *laissez-faire* individualist liberalism of Herbert Spencer and, to a lesser extent, of J.S. Mill, and to advocate a more collectivist liberalism in which the state seeks to promote the positive liberty of its members.

RICHARD BELLAMY

GRICE, HERBERT PAUL (1913–88)

Grice was a leading member of the post-war Oxford group of analytic philosophers. His small body of published work, together with an oral tradition, has been deeply influential among both philosophers and theoretical linguists. His outline of general rules of conversation began a new era in pragmatics. Grice's analysis of speaker's meaning explicates semantic notions in terms of the psychological concepts of intention and belief. His theory of conversation is based on the nature of language as a rational, cooperative activity. His account of conversational rules gave him a tool that he applied to a wide class of philosophical problems. Although Grice is most famous for his work on language and meaning, his interests cover a full range of philosophical topics, including ethics, moral psychology and philosophical psychology.

JUDITH BAKER

GROSSETESTE, ROBERT (*c.*1170–1253)

Grosseteste's thought is representative of the conflicting currents in the intellectual climate of Europe in the late twelfth and early thirteenth centuries. On the one hand, his commitment to acquiring, understanding and making accessible to his Latin contemporaries the texts and ideas of newly discovered Arabic and Greek intellectual traditions places him in the vanguard of a sweeping movement transforming European thought during his lifetime. His work in science and natural philosophy, for example, is inspired by material newly translated from Arabic sources and by the new Aristotelian natural philosophy, especially the *Physics*, *On the Heavens* and *Posterior Analytics* (Aristotle's treatise on the nature of scientific knowledge). Similarly, in his work in metaphysics, ethics and theology Grosseteste turns to ancient sources previously unknown (or incompletely known) to Western thinkers, prominent among which are Aristotle's *Ethics* and the writings of Pseudo-Dionysius. His work as a translator of and commentator on Aristotle and Pseudo-Dionysius places Grosseteste among the pioneers in the assimilation of these important strands of the Greek intellectual heritage into the mainstream of European thought.

On the other hand, Grosseteste's views are in significant respects conservative. His greatest debt is to Augustine, and his most original ideas – such as his view that light is a fundamental constituent of all corporeal reality – are extensions of recognizably Augustinian themes. Moreover, although his work on Aristotle is groundbreaking, his approach is judicious and measured, lacking any hint of the crusader's zeal that marks the work of the later radical Aristotelians. In general his practice conforms to the traditional Neoplatonist line, viewing Aristotle as a guide to logic and natural philosophy while turning to Platonism – in Grosseteste's case, Augustinian and Pseudo-Dionysian Platonism – for the correct account of the loftier matters of metaphysics and theology.

SCOTT MACDONALD

GROTIUS, HUGO (1583–1645)

Scholar, lawyer and statesman, Grotius contributed to a number of different disciplines. His reputation as the founder both of a new international order and of a new moral science rests largely on his *De iure belli ac pacis* (The Law of War and Peace) (1625). Though the tendency today is to regard Grotius as one figure among others in the development of the concept of international law, he is increasingly regarded as one of the most original moral philosophers of the seventeenth century, in particular as having laid the foundations for the post-sceptical doctrine of natural law that flourished during the Enlightenment.

GURNEY, EDMUND (1847–88)

Edmund Gurney was an English psychologist and musician. His major work, *The Power of Sound*, is a vast treatise on musical aesthetics, ranging from issues in the physiology of hearing to the question of the relation of music to morality, but is mostly devoted to central questions of form, expression and

value in music. It is the most significant work of its kind in the latter half of the nineteenth century.

Commentators often couple Gurney with Hanslick as a supporter of musical formalism, but his views on the expressive dimension of music are neither as restrictive nor as doctrinaire as Hanslick's. Hanslick insisted on denying specific emotional content to music, allowing it only to convey dynamic features, which emotions, among other things, might exhibit. Gurney, on the other hand, grants that some music possesses fairly definite emotional expression, and discusses at length the grounds of such expression; he is primarily concerned to deny that musical impressiveness, or beauty, is either the same as or depends on musical expressiveness.

Gurney maintains that overall form in music is not of primary relevance to the appreciation of music. This is because the central feature of musical comprehension is the grasping of individual parts as they occur, and the grasping of connections to immediately neighbouring parts, whatever the overarching form of a piece might be. The value of a piece is directly a function of the pleasurableness of its individual parts and the cogency of sequence exhibited at the transitions between them, not a function of its global architecture.

JERROLD LEVINSON

H

HABERMAS, JÜRGEN (1929–)

Jürgen Habermas, German philosopher and social theorist, is perhaps best known for his wide-ranging defence of the modern public sphere and its related ideals of publicity and free public reason, but he has also made important contributions to theories of communication and informal argumentation, ethics, and the foundations and methodology of the social sciences. He studied in Göttingen, Zurich and Bonn, completing a dissertation on Schelling's philosophy in 1954. After working for a short time as Theodor Adorno's research assistant at the Institute for Social Research in Frankfurt he held professorships in Heidelberg and Frankfurt and, from 1971 to 1981, was co-director of the Max Planck Institute in Starnberg. With the publication of *Knowledge and Human Interests* (1968) he became widely recognized as the leading intellectual heir to the Frankfurt School of Critical Theory, a variant of Western Marxism that included such figures as Adorno, Max Horkheimer and Herbert Marcuse. His two-volume *The Theory of Communicative Action* (1981) is a major contribution to social theory, in which he locates the origins of the various political, economic and cultural crises confronting modern society in a one-sided process of rationalization steered more by the media of money and administrative power than by forms of collective decision-making based on consensually grounded norms and values.

KENNETH BAYNES

HAECKEL, ERNST HEINRICH (1834–1919)

Haeckel was the leading German Darwinist. His evolutionary philosophy of monism differed substantially from the views of Darwin or British evolutionary philosophers such as Herbert Spencer or the dualist T.H. Huxley. Haeckel's monism asserted the unity of physical and organic nature, and included mental processes and social phenomena. Its initial form was mechanistic, seeking to reduce vital processes to physicochemical laws and substances. However, his efforts to construct the history of life meant that Haeckel became preoccupied with historical processes. In its final form, his monism was pantheistic. Although Haeckel has been regarded as a forerunner of national socialism, a contextual reading of his works does not support this interpretation.

PAUL WEINDLING

HALAKHAH

The central ideal of rabbinic Judaism is that of living by the Torah, that is, God's teachings. These teachings are mediated by a detailed normative system called *halakhah*, which might be translated as 'the Way'. The term 'rabbinic law' captures the form of *halakhic* discourse, but not its range. Appropriate sections of *halakhah* have indeed served as the law of Jewish communities for two millennia. But other sections relate to individual conscience and religious observance and are enforceable only by a 'heavenly court'.

Although grounded in Scripture, *halakhah*'s frame of reference is the 'oral Torah', a tradition of interpretation and argument culminating in the twenty volumes of the Talmud. God's authority is the foundational norm, but it is only invoked occasionally as superseding human understanding. Indeed, the rabbis disallowed divine interference in their deliberations, asserting, in keeping with Scripture, that Torah is 'not in heaven' (Bava Metzia 59b, citing Deuteronomy 30: 12).

Given the lack of binding dogma in Judaism, *halakhic* practice has often been regarded as the common denominator that unites the Jewish community. The enterprise of furnishing 'reasons of the commandments' (*ta'amei ha-mitzvot*), central to many thinkers in Judaism, accordingly reveals a great diversity of orientations. These range, in

medieval Judaism, from esoteric mystical doctrines to Maimonides' rational and historical explanations; and among modern writers, from moral positivism to existentialism.

NOAM J. ZOHAR

HANSLICK, EDUARD (1825–1904)

Eduard Hanslick, a music critic for the popular Viennese press, is principally known as the author of *Vom Musikalisch-Schönen* (1854). This is probably the most widely read work in the aesthetics of music for both philosophers and musicians, and remains the starting point for any discussion either of the place of emotion in music, or of the doctrine usually referred to as 'musical purism'. On the former, Hanslick maintained what he calls the negative thesis, which 'first and foremost opposes the widespread view that music is supposed to represent the feelings'; on purism, he proposed the positive thesis or antithesis, 'that the beauty of a piece of music is specifically musical, that is, is inherent in the tonal relationships without reference to an extraneous, extra-musical context'.

PETER KIVY

HAPPINESS

In ordinary use, the word 'happiness' has to do with one's situation (one is fortunate) or with one's state of mind (one is glad, cheerful) or, typically, with both. These two elements appear in different proportions on different occasions. If one is concerned with a long stretch of time (as in 'a happy life'), one is likely to focus more on situation than on state of mind. If a short period of time, it is not uncommon to focus on states of mind.

By and large philosophers are more interested in long-term cases. One's life is happy if one is content that life has brought one much of what one regards as important. There is a pull in these lifetime assessments towards a person's objective situation and away from the person's subjective responses. The important notion for ethics is 'wellbeing' – that is, a notion of what makes an individual life go well. 'Happiness' is important because many philosophers have thought that happiness is the only thing that contributes to wellbeing, or because they have used 'happiness' to mean the same as 'wellbeing'.

What, then, makes a life go well? Some have thought that it was the presence of a positive feeling tone. Others have thought that it was having one's desires fulfilled – either actual desires (as some would say) or informed desires (as others would say). It is unclear how stringent the requirement of 'informed' must be; if it is fairly stringent it can, in effect, require abandoning desire explanations and adopting instead an explanation in terms of a list of good-making features in human life.

HARMONIA

See Pythagoreanism

HART, HERBERT LIONEL ADOLPHUS (1907–93)

H.L.A. Hart, Professor of Jurisprudence at Oxford University, 1952–68, is an outstanding representative of the analytical approach in jurisprudence and philosophy of law. He restated 'legal positivism' in the tradition of Jeremy Bentham and John Austin, differentiating between law's existence and its moral qualities. But he rejected the Benthamite identification of law with a sovereign's commands, advancing instead a theory of law as comprising a special, systematically organized, kind of social rules. He did this in a linguistic-analytical style, showing how attention to our way of speaking and thinking about rules can yield new insights into their nature.

NEIL MACCORMICK

HASIDISM

Its name literally meaning pietism, Hasidism is a mystical renewal movement that originated in Eastern Europe in the mid-eighteenth century. It has become one of the most important spiritual and social developments of Orthodox Judaism and has exerted an influence as well on non-Jews and Jews who are not Orthodox. Early Hasidic leaders claimed their spiritual authority on the basis of heavenly revelations and mystical awakenings. But they generally differed from the more esoterically minded Kabbalists, from whom they drew their earliest following, in seeking to present the fruits of mystical inspiration to the community. Hasidic teachings fostered specific spiritual and ritual innovations, which gave outward expression to the profound nexus that the Hasidic masters saw between mundane existence and the inner, mystical meaning of God's law. According to Hasidic thinking, the divine and the human formed a single, all-encompassing unity, and it was on this basis that the Hasidic rabbis found in acts of Jewish piety means of linking divine experience with

human responsiveness. Notable for its vitality and continuity in diversity, Hasidism continues its influence on religious Jewry and beyond to the present day.

RACHEL ELIOR

HEAVEN

In Christian theology, heaven is both the dwelling place of God and the angels, and the place where all who are saved ultimately go after death and judgment to receive their eternal reward. The doctrine of the resurrection of the body requires that heaven be a place because it must contain the glorified bodies of the redeemed, but heaven is more theologically important as a state than as a place. This state is traditionally described as involving the most intimate union with God without the elimination of the individual human personality (the beatific vision); it is a state of perfect bliss beyond anything possible on earth. In high medieval theology, the happiness of heaven is understood to be so great that it is even beyond the capability of human nature to enjoy without divine aid. There are varying views on the nature of heavenly society, however, with some theologians (Augustine, Aquinas, Bonaventure) arguing that perfect happiness will be derived from the love of God alone, while others (for example, Giles of Rome) stress the joy that will be derived from the company of the elect. More recently, interest in the nature of heaven has declined, and Christian theology has tended to play down its importance.

LINDA ZAGZEBSKI

HEDONISM

Hedonism is the doctrine that pleasure is the good. It was important in ancient discussions, and many positions were taken, from the view that pleasure is to be avoided to the view that immediate bodily pleasure is to be sought. More elevated views of pleasure were also taken, and have been revived in modern times. There are three varieties of hedonism. Psychological hedonists hold that we can pursue only pleasure; evaluative hedonists that pleasure is what we ought to pursue; reflective hedonists that it is what on reflection gives value to any pursuit. Arguments for psychological hedonism suggest that an agent's actions are a function of what they think will maximize their pleasure overall. Explaining altruism can lead such theories into truism. Similar arguments are used for reflective hedonism, and the same problem arises. The difficulty for evaluative hedonism lies in deciding how we can establish certain ends as desirable. The claim that pleasure is to be maximized seems immoral to many. Hedonism also faces problems with the measurement of pleasure.

JUSTIN GOSLING

HEGEL, GEORG WILHELM FRIEDRICH (1770–1831)

Introduction

Hegel was the last of the main representatives of a philosophical movement known as German Idealism, which developed towards the end of the eighteenth century primarily as a reaction against the philosophy of Kant, and whose main proponents, aside from Hegel, include Fichte and Schelling. The movement played an important role in the philosophical life of Germany until the fourth decade of the nineteenth century. Like the other German Idealists, Hegel was convinced that the philosophy of Kant did not represent the final word in philosophical matters, because it was not possible to conceive a unified theory of reality by means of Kantian principles alone. For Hegel and his two idealistic predecessors, a unified theory of reality is one which can systematically explain all forms of reality, starting from a single principle or a single subject. For Hegel, these forms of reality included not only solar systems, physical bodies and the various guises assumed by organic life, for example, plants, animals and human beings, but also psychic phenomena, social and political forms of organization as well as artistic creations and cultural achievements such as religion and philosophy. Hegel believed that one of the essential tasks of philosophy was the systematic explanation of all these various forms starting from one single principle, in other words, in the establishment of a unified theory of reality. He believed this because only a theory of this nature could permit knowledge to take the place of faith. Hegel's goal here, namely the conquest of faith, places his philosophical programme, like that of the other German Idealists, within the wider context of the philosophy of the German Enlightenment.

For Hegel, the fundamental principle which explains all reality is reason. Reason, as Hegel understands it, is not some quality which is

attributed to some human subject; it is, by contrast, the sum of all reality. In accordance with this belief, Hegel claims that reason and reality are strictly identical: only reason is real and only reality is reasonable. The considerations which moved Hegel to identify reason with reality are various. On the one hand, certain motives rooted in Hegel's theological convictions play a role. According to these convictions, one must be able to give a philosophical interpretation of the whole of reality which can simultaneously act as a justification of the basic assumptions of Christianity. On the other hand, epistemological convictions also have to be identified to support Hegel's claim that reason and reality are one and the same. Among these convictions belong the assumptions (1) that knowledge of reality is only possible if reality is reasonable, because it would not otherwise be accessible to cognition, and (2) that we can only know that which is real.

According to Hegel, although reason is regarded as the sum total of reality, it must not be interpreted along the lines of Spinoza's model of substance. Reason is rather to be thought of as a process which has as its goal the recognition of reason through itself. Since reason is the whole of reality, this goal will be achieved when reason recognizes itself as total reality. It is the task of philosophy to give a coherent account of this process which leads to self-knowledge of reason. Hegel conceived this process by analogy with the model of organic development which takes place on various levels. The basic presupposition governing the conception of this process is that reason has to be interpreted in accordance with the paradigm of a living organism. Hegel thought of a living organism as an entity which represents the successful realization of a plan in which all individual characteristics of this entity are contained. He called this plan the concept of an entity, and conceived its successful realization as a developmental process, in the course of which each of the individual characteristics acquires reality. In accordance with these assumptions, Hegel distinguished the concept of reason from the process of the realization of this concept. He undertook the exposition of the concept of reason in that section of his philosophical system which he calls the *Wissenschaft der Logik* (*Science of Logic*). In this first part of his system, the various elements of the concept of reason are discussed and placed into a systematic context. He presented the process of the realization of this concept in the other two parts of his system, the *Philosophie der Natur* (*Philosophy of Nature*) and the *Philosophie des Geistes* (*Philosophy of Spirit*). Apart from their systematic function, which consists in demonstrating reason in the Hegelian sense as total reality, both parts have a specifically material function in each case. In the *Philosophy of Nature*, Hegel aims to describe comprehensively all aspects of natural phenomena as a system of increasingly complex facts. This system begins with the simple concepts of space, time and matter and ends with the theory of the animal organism. The *Philosophy of Spirit* treats of various psychological, social and cultural forms of reality. It is characterized by the assumption of the existence of something like genuine, spiritual facts, which cannot be described as subjective states of individual persons possessing consciousness, but which have an independent, objective existence. For Hegel, examples of such facts are the state, art, religion and history.

In spite of the relatively abstract metaphysical background of his philosophy, which is difficult to reconcile with common sense, Hegel's insights in his analysis of concrete facts have guaranteed him a permanent place in the history of philosophy. None the less, for contemporary readers these insights are interesting hypotheses, rather than commonly accepted truths. Of lesser importance among these insights should be counted Hegel's results in the realm of natural philosophy, which soon suffered considerable criticism from practising natural scientists. The important insights apply more specifically to the spheres of the theory of knowledge as well as the philosophy of right, and social and cultural philosophy. Hegel is thus regarded as an astute and original representative of the thesis that our conception of objectivity is largely determined by social factors which also play a significant role in constituting the subject of cognition and knowledge. His criticisms of the seventeenth- and eighteenth-century concepts of natural law and his thoughts on the genesis and significance of right in the modern world have had a demonstrable influence on the theory of right in juridical contexts. Hegel's analysis of the relationship and interplay between social and political institutions became a constituent element in very influential social theories, in particular that of Marx. The same applies to his central theses on the theory of art and the philosophy of religion and history. Hegel's thoughts on the history of philosophy made that topic a philosophical discipline in its own right. Thus Hegel was a very influential philosopher. That his philosophy has none the less remained deeply contentious is due in part to the fact that his uncompromising struggle against traditional habits of thought and his attempt to establish a conceptual perspective on reality in contrast with the philosophical tradition of the time remains characterized by a large measure of obscurity and vagueness. Unfortunately these characteristics also infect every summary of his philosophy.

1 Life and works

Hegel was born on 27 August 1770 in Stuttgart, son of a Württemberg official. In the autumn of 1788, after attending the local grammar school, he began a course of study at the Protestant Seminary in Tübingen in preparation for a career as a Protestant clergyman. Two of his fellow students and friends were F.W.J. SCHELLING and F. Hölderlin. In autumn 1793, after successfully completing this period of study, Hegel became a private tutor in Berne, Switzerland, and remained there until 1796. From January 1797 until the end of 1800 he was a private tutor in Frankfurt am Main, where he again came into contact with Hölderlin, who played an important role in the formation of Hegel's early philosophical convictions. Thanks to a legacy, Hegel was able to abandon his position as a tutor and pursue his academic ambitions. Early in 1801 he went to Jena. His student friend Schelling had become Fichte's successor and was lecturing in philosophy at the university there. With Schelling's energetic support Hegel qualified as a *Privatdozent* in the autumn of 1801 with a thesis on natural philosophy. Initially, Schelling and Hegel worked closely together, a fact which is documented by a philosophical periodical which they published jointly from 1802 (although it ceased publication following Schelling's departure from Jena in 1803). In 1805 Hegel was appointed Extraordinary Professor, but financial difficulties forced him to abandon his activities at the University of Jena in the autumn of 1806. A friend's intervention enabled him to take over as editor of a daily newspaper in Bamberg in March 1807. In November 1808 the same friend then ensured that Hegel was nominated rector and professor at a grammar school in Nuremberg. After a few years in this capacity, Hegel was able to return to university life. In 1816 he was called to the University of Heidelberg, which he left again in 1818 to take a chair at the University of Berlin, as Fichte's successor. There he revealed a considerable talent for academic teaching and succeeded in assuring a dominant position in contemporary discussions for his philosophical doctrines. Hegel died in Berlin during a cholera epidemic on 14 November 1831, at the height of his fame.

Hegel's works can be divided into three groups: (1) texts written by Hegel and published during his lifetime; (2) texts written by him, but not published during his lifetime; and (3) texts neither written by him nor published during his lifetime. Two texts from his early years in Frankfurt do not fit into this scheme. The first is the translation of a pamphlet by Cart, a Berne lawyer, on the political situation in the Canton of Vaud, which was translated and annotated by Hegel, and which he published anonymously in 1798. This is the first printed text by Hegel; the second is a fragment dating from the same period and known as the *Systemprogramm des deutschen Idealismus* (System-Programme of German Idealism). The text has survived in Hegel's handwriting, but his authorship remains controversial.

The earliest writings in the first group date from the beginning of Hegel's time in Jena. His first philosophical work is entitled *Differenz des Fichte'schen und Schelling'schen Systems der Philosophie* (*The Difference between Fichte's and Schelling's System of Philosophy*) (1801). This was followed later during the same year by the essay which he had to submit in order to qualify as *Privatdozent*, *De Orbitis Planetarum* (On the Orbits of the Planets). In 1802–3 Hegel published various philosophical works in the periodical which he edited with Schelling, the *Kritisches Journal der Philosophie* (Critical Journal of Philosophy). The most important among these were *Glauben und Wissen* (Faith and Knowledge), *Verhältnis des Skeptizismus zur Philosophie* (The Relationship of Scepticism to Philosophy) and *Über die wissenschaftlichen Behandlungsarten des Naturrechts* (On the Scientific Ways of Dealing with Natural Law). Immediately after his period as a university teacher in Jena and at the beginning of his period in Bamberg, Hegel published his first great philosophical work, the *Phänomenologie des Geistes* (*Phenomenology of Spirit*) (1807). During the eight years in which he taught at the grammar school in Nuremberg, Hegel published his three-volume *Wissenschaft der Logik* (*Science of Logic*) (1812, 1813, 1816). While in Heidelberg, the complete presentation of his system appeared for the first time, in his *Enzyklopädie der philosophischen Wissenschaften im Grundrisse* (*Encyclopedia of the Philosophical Sciences in Outline*) (1817), which was reprinted twice during his Berlin period in two completely revised editions (1827, 1830). Also during this period he published *Naturrecht und Staatswissenschaft im Grundrisse. Grundlinien der Philosophie des Rechts* (Natural Law and Politics in Outline. The Principles of the Philosophy of Right) (1821). Apart from these, Hegel published only minor writings during his lifetime. These were written partly in response to events at the time, although most articles were for the *Jahrbücher für wissenschaftliche Kritik* (Yearbooks of Scientific Criticism), which he co-edited from 1827. Among these is his final published work, *Über die englische Reform-Bill* (On the English Reform Bill) (1831).

The second group of texts includes those works which were written by Hegel but not published by him. Almost all these texts first became accessible in

a more or less authentic form during the twentieth century. They can again be divided into three groups. The first group consists of the manuscripts which Hegel wrote between the end of his time as a student and the end of his time in Jena. Among the most important are the so-called *Theologische Jugendschriften* (*Early Theological Writings*), which were published in 1907 at the instigation of Wilhelm Dilthey by his pupil, H. Nohl. Today they are known as Hegel's *Frühschriften* (Early Writings). Further important texts from this period are the three *Jenaer Systementwürfe* (*Jena Drafts of a Philosophical System*), written between 1803 and 1806, partly for publication and partly as lecture notes. The second group of writings not published by Hegel consists of works produced during his period in Nuremberg. Hegel's first biographer, K. Rosenkranz, presented excerpts from these writings as the *Philosophische Propädeutik* (Philosophical Propaedeutic) (1840). In this text Hegel attempted to present his philosophical views in a form suitable for use within the framework of his grammar-school teaching courses. The third group of texts comprises manuscripts and notes which he wrote in connection with his lectures in Heidelberg and Berlin. They are partly contained in the editions in which his pupils and friends published his works after his death.

The third major group of texts covers those works which were neither written nor published by Hegel. They form almost half the texts contained in the first complete edition of Hegel's works. Among them one finds Hegel's extremely influential lectures on aesthetics, the philosophy of history, the history of philosophy and the philosophy of religion. In the form in which they have become influential, these texts are the product of students, in most cases representing the result of notes compiled during Hegel's lectures. Insufficient attention has been paid to this remarkable fact, that is, that some of Hegel's most influential texts actually have the status of second-hand sources.

The first complete edition of Hegel's work, published during the years 1832–45, proved to be influential but highly unreliable both from a historical and a critical point of view. Since the beginning of the twentieth century several attempts have been made to produce a new edition. To date, none has reached a successful conclusion. Since 1968 a new historical and critical edition of Hegel's complete works has been in preparation. By the end of 2003 eighteen volumes had been published.

2 The development of the system: the early writings

The early years of Hegel's intellectual career were characterized less by philosophical ambitions than by interests in public enlightenment and public education. In contrast to his student friends Hölderlin and Schelling, whose activities were directly based on internal philosophical discussions, Hegel aimed in his early works to find ways 'to influence men's lives' (as he wrote to Schelling). He regarded as an appropriate starting point for these attempts the analysis of the role and consequences which must be attributed to religion, especially Christianity, for the individual and for the social context of a nation. In this early approach two different interests are at work. On the one hand, Hegel aims to show how religion had developed into a power hostile to life, which produces its effect through fear and demands submission. On the other hand, however, he would like to understand the conditions under which it can prosper as a productive element in the life of the individual and society. Hegel's investigations of religion under these two aspects were strongly influenced during the early years (1793–1800) by the cultural criticism and social theories of ROUSSEAU as well as the religious philosophy of KANT (§§11, 13), and by his critical assessment of the theological positions of his academic theology teachers in Tübingen (G.C. Storr and J.F. Flatt). The most important works during this period are represented by the texts which have been preserved as fragments, and which have become known under the titles *Die Positivität der christlichen Religion* (The Positivity of the Christian Religion) (1795–6) and *Der Geist des Christentums und sein Schicksal* (The Spirit of Christianity and its Fate) (1798–9).

Hegel's religious criticism centres on the concept of 'positive religion'. For Hegel, a positive religion is one whose fundamental content and principles cannot be made comprehensible to human reason. They thus appear unnatural and supernatural, and are seen to be based on authority and to demand obedience. For Hegel, the Jewish religion represents the paradigm of a positive religion. Hegel also considers that the Christian religion has been transformed into a positive religion during the course of its history, in other words into a religion which alienates human beings from themselves and from their fellow creatures (see ALIENATION). He tries to identify cultural and social developments as an explanation for this transformation. In direct opposition to positive religion, Hegel conceives what he calls 'natural religion', which he defines as one whose doctrines correspond with human nature: one which permits or even encourages people to live not only in harmony with their own needs, inclinations and well-considered convictions, but also without being alienated from other people. Hegel's belief in the value for mankind of harmony with oneself (and others), which is strongly

influenced by the Stoic ethic (which also via Rousseau had an impact on Kant's practical philosophy), is grounded in a quasi-metaphysical conception of love and life. It owes a considerable debt to the philosophical approach of Hölderlin, with whom Hegel again associated closely during his Frankfurt period. According to this conception, there is a sort of moral emotion of love, which rises above all separations and conflicts, in which persons might be involved in relation to themselves and to others. It is this emotion of love which makes people aware of their unity with others and with themselves. It cannot be adequately thematized by philosophy, which is based on reflection and (conceptual) distinction. It demonstrates vividly, however – and here metaphysics enters – the true constitution of reality, which consists of a state of unity forming the basis for all separations and conflicts and making these possible. This reality, which has to be thought of as unity, Hegel calls 'Life' (*Leben*) and also 'Being' (*Sein*). Hegel's efforts at the end of his Frankfurt period are directed towards thinking of reality in these terms in a sufficiently differentiated manner. In doing so he pursues above all the goal of conceiving of life as a process which generates as well as reconciles oppositions, a dynamic unity of generation and reconciliation. To explain this complex structure, which he conceives what he calls 'life' to be, Hegel devised in the so-called *Systemfragment von 1800* the formula 'Life is the connection of connection and non-connection'. This formula and the concept of life on which it is based already point clearly towards Hegel's later organicist metaphysics.

3 The development of the system: the Jena writings

The work of Hegel's Jena period (1801–6) can be divided into critical and systematic writings. Among the critical writings are his first philosophical publication, *The Difference between Fichte's and Schelling's Systems of Philosophy*, and most of the essays which he published during the years 1802–3 in the *Critical Journal of Philosophy*. In these essays, Hegel reveals himself as a critic of the philosophy of his age, especially of the positions of Kant, Jacobi and Fichte whom he accuses of practising a 'reflective philosophy of subjectivity' as he calls it in the sub-title of his essay *Faith and Knowledge* (1802). For Hegel, reflective philosophy is initially an expression of an age or historical situation. Such an age is subject to the dichotomies of culture (*Bildung*), which are the products of the understanding and whose activity is regarded as divisive and isolatory. Being subject to those dichotomies, it is impossible for such an age to overcome them and restore the harmony which the understanding has destroyed. A philosophy committed to such an age shares its fate, being also unable to remove, at least in theory, the conflicts which appear as the concrete forms of dichotomy. For even when philosophy strives to overcome these conflicts – according to Hegel, 'the only interest of reason' – and thus makes reference to a particular idea of unity or harmony, even then it remains committed to the conditions of its age and will achieve nothing except newer and even more acute conflicts. According to Hegel, we can characterize the general form underlying the various conflicts as the conflict between subjectivity and objectivity. The attempts of reflective philosophy to overcome them fail, in Hegel's view, because they are largely abstract: that is, they fail to take into account either the subjective or the objective component of the conflict, and declare it to be resolved by neglecting or abstracting from either of these components. In abstracting from subjectivity, objectivity (in Hegel's terminology) is posited as absolute, which leads to the subordination of subjectivity. This way of reconciling the conflict between subjectivity and objectivity is characteristic of all religions describable as positive by Hegel's definition. If, on the other hand, abstraction is made from objectivity, and subjectivity is thus posited as absolute, then objectivity is regarded as being dependent on subjectivity. This one-sided absolutization of subjectivity is Hegel's objection to the philosophies of Kant, Jacobi and Fichte and the reason he describes their theories as forms of a reflective philosophy of subjectivity.

During his early years in Jena, in contrast to the philosophical attitudes which he criticized, Hegel assumes along with Schelling that the described conflict between subjectivity and objectivity can only be overcome by a philosophy of identity. A philosophy of identity is characterized by the preconditions (1) that for each opposition there is a unity which must be regarded as a unity of the opposing factors, and (2) that the opposing factors are nothing more than their unity under the description or *in the form* of the opposing factors. These preconditions suggest that one should understand the overcoming of the opposition between subjectivity and objectivity as a single process which *reconstructs* the unity underlying the opposing factors and makes them possible in the first place. Following the conceptual assumptions favoured by Hegel at the time, the unity to be reconstructed in a philosophy of identity is defined as the 'subject-object', and the subject and object themselves are characterized as 'subjective subject-object' or 'objective subject-object' respectively. The process of reconstruction of the subject-object by means of the assumptions of the philosophy of identity

consists of recognizing the subjective and objective subject-object in their specific one-sidedness or opposition to each other, and thus gaining an insight into the internal structure of the subject-object as the unity which underlies the two conflicting factors and makes them possible in the first place. Although Hegel did not persist in using this terminology for long, for most of his time in Jena he nevertheless remained faithful to the project of the development of a unity which he considered to be comprehensive and which consists of its internal opposing elements. The various attempts at a formal description of a process which was aimed at a unity led Hegel to various system models. All of them contained – albeit with variations of terminology and detail – a discipline initially defined by Hegel as 'logic and metaphysics' as well as a so-called 'real philosophy' (*Real-Philosophie*), in other words a 'philosophy of nature' as well as what he later called a 'philosophy of spirit'.

The systematic works of the Jena period, apart from the *Phenomenology of Spirit*, principally include the three *Jena Drafts of a Philosophical System*. Of these (in some cases) comprehensive fragments, mainly the sections dealing with the philosophy of nature and of spirit are extant. As regards the philosophy of nature, in all the Jena versions of this part of Hegel's system the description of all natural phenomena, the analysis of their processes and their interrelationships is achieved by recourse to two essential factors, which Hegel calls 'Ether' and 'Matter' (*Materie*). 'Ether' describes something like a materialized absolute, which expresses and develops itself within the realm of space and time. This entity is now introduced by Hegel in connection with the development of the determinations of nature as absolute matter or alternatively as absolute being, and the task of philosophy of nature lies in interpreting the various natural phenomena – from the solar system and the laws governing its movements to illness and death of animal organisms – as different manifestations of this absolute matter. Hegel is concerned not merely to show that any particular natural phenomenon is in its peculiar way a specific expression of absolute matter. Above all, he is concerned to prove that nature is a unity ordered in a particular manner. As a specific expression of absolute matter, each natural phenomenon represents an element in the ordered succession of natural phenomena. The position of a natural phenomenon in the order of nature is laid down by the specific way in which absolute matter is expressed in it. A consequence of this approach is that here the natural order is understood as determined by certain postulates which result from the structural conditions of the absolute matter and the methodological maxims of the complete description of these conditions. Differences between the Jena versions of Hegel's philosophy of nature mainly result from the inclusion of new facts made available by current science; but they leave his basic assumptions untouched.

Things are different in the case of the Jena writings on the second part of real philosophy – the philosophy of spirit – initially still described by Hegel as the 'philosophy of ethical life' (*Philosophie der Sittlichkeit*). They reveal many changes, all linked to modifications of his conception of spirit. Initially, he presents his philosophy of spirit as a theory of ethical life, which he then transforms into a theory of consciousness. For reasons linked to a renewed preoccupation with Fichte and certain new insights into the logical structure of self-consciousness, towards the end of his Jena period Hegel found himself obliged to present an approach which had occupied him since at least 1804–5. This approach enabled him to liberate the philosophy of spirit from its narrow systematic links to a conception of ethical life based on assumptions incompatible with his new conception of spirit. It assumes that only the formal structure of self-consciousness, which consists in its being a unity of generality and singularity, can provide the framework within which the logical-metaphysical determinations, the natural world and psychosocial phenomena unite to form a meaningful systematic context. For the philosophy of spirit this means in particular that as far as method is concerned it is better equipped for the implementation of its systematic task of being the representation of the processes of self-realization of what Hegel calls 'reason'. This insight into the formal structure of self-consciousness is the final achievement of his Jena period, and one which he never subsequently abandoned.

4 The system: metaphysical foundations

Hegel's systematic philosophy attempts to comprehend reality in all its manifestations as a self-representation of reason (*Vernunft*). His conception of what he calls 'reason' combines various specifically Hegelian connotations, both ontological and epistemological. For him, 'reason' is not merely the name for a human faculty which contributes in a specific manner to our gaining knowledge; he also uses 'reason' to describe that which is ultimately and eminently real. This is the ontological connotation. Reason is reality, and that alone is truly real which is reasonable. This programmatic credo, which has become famous from the foreword to Hegel's *Philosophy of Right*, is the basic precept determining the entire approach to his system.

At least three different convictions make up this basic precept of the ontological dignity of reason.

The first is that the everything which in one sense or another is real must be considered as the differentiation and partial realization of a primary structure which in turn forms the basis for whatever is real in whichever sense. Hegel calls this primary structure 'the absolute' or 'reason'. He shares this conviction of the necessity of assuming a primary structure he called 'reason' (interpreted ontologically) with Fichte, Schelling, Hölderlin and other members of the post-Kantian idealistic movement who used different names for it. It is this assumption which makes them all (ontological) monists. For Hegel this conviction is justified not only because it alone offers a basis for systematic philosophical considerations, following the failure of all previous philosophical attempts to conceive of a unified and complete representation of the world. It is also justified because, according to Hegel, without it one cannot make sense of the concepts of an object and of objectivity. This latter justification is part of the task of his *Phenomenology of Spirit*

This first conviction, which forms a part of Hegel's ontological conception of reason, is still too imprecise to provide a clue as to why exactly the concept 'reason' can be used to characterize the primary structure. Hegel's second important conviction, however, makes this clearer. It relates to the internal constitution of the structure which he characterizes as reason. He understands this structure to be a complex unity of thinking and being. The relevant motives for this conviction can be summarized as follows: the only philosophical approach which can organize the whole of reality into a unified and coherent picture accessible to knowledge is one which insists that everything taken to be real is only real inasmuch as it can be comprehended as the actualization of some specific structural elements of reason. This assertion of the essential reasonableness of all being, together with the first conviction of the necessity of assuming a primary structure, leads directly to the concept of this primary structure as a unity of thinking and being, understood in the very radical sense that thinking and being are one and the same, or that only thinking has being. If we now call this unity of thinking and being 'reason', and if, like Hegel, we are convinced that the requisite primary structure must be thought of as this unity of thinking and being, then reason will be declared on the one hand to represent what in the final analysis is ultimately real, and on the other that which alone is real. Since a monistic position is one in which a single entity is maintained as the ultimate and sole reality, Hegel's philosophical conception has rightly been called a 'Monism of Reason' (see MONISM).

The third conviction which enters into Hegel's basic assumption of reason as the primary structure constituting reality and thus being ultimately and only real is that this structure constitutes reality and thus its own objectivity in a teleological process which must be understood as a process of cognition. It is this conviction which leads to the characteristically Hegelian dogma that there can be no adequate theory of reality without a dynamic or process-oriented ontology (see PROCESSES). The formula which Hegel uses to characterize this process from his early Jena works onwards shows very clearly the dominant role which he assigns to what he defines as 'reason' in the systematic approach designed to elaborate his third conviction. This process is described as 'self-knowledge of cognition' (*Selbsterkenntnis der Vernunft*). Hegel tries to integrate within this formula various aspects of his conception of reason. The first aspect is that it is necessary to take reason, understood as the primary structure, as something which is essentially dynamic. By this he means that the element of self-realization forms part of the moments which determine the primary structure. It is difficult to understand the way in which Hegel links this element of self-realization into his idea of reason as the unity of thinking and being. In order to get a rather over-simplified idea of the background for Hegel's claim, it might help to rely metaphorically on the theory of organism: just as an organism can be described as an entity whose development is linked to the concept or the structural plan of itself in such a way that the (more or less) successful realization of this concept or structural plan belongs to its being real, so we should think of Hegelian reason, understood as the ontologically relevant primary structure, as realizing in a quasi-organic developmental process the unity of thinking and being which characterizes its concept, thereby representing itself as real or as reality.

The second aspect Hegel has in mind when he speaks of 'self-cognition of reason', describing a process which must indeed be understood as that of the self-realization of reason, is that this process represents a process of *cognition* for reason. It is apparently not sufficient for Hegel to embed his idea of reason as the ontological primary structure in a conception of realization based on the paradigm of the organism. Such a grounding seems to be too unspecific for him, because it does not show how to describe a process which is typical of *all* organisms in such a way that we understand more precisely and in detail what it means for the process to be one of self-realization of *reason*. The specific way in which reason realizes itself is to be characterized first of all as a process of cognition, because only this characterization takes into account the fact that that which is being realized, namely reason, must be thought of strictly as nothing more than thinking

qua cognition. But even this way of conceiving the realization of reason is still too imprecise, unless one includes in the concept of realization the thesis that reason is the ultimately and only real ontological primary structure. The inclusion of this thesis then leads directly to the teleologically conceived description of the process of the realization of reason as a process of self-cognition. For if only reason – by which is meant the unity of thinking and being – is real, and if an integral part of this concept of reason is the conception of its realization in the form of a process of cognition, then this process can only be directed towards the cognition of reason itself, because nothing else exists. Since this process aims to make reason aware that it alone is real, the presentation of this process, in Hegel's view, must take on the form of a system in which each manifestation of reality documents its reasonable nature. His philosophy aims to elaborate this system.

The project of exhibiting reason not only as the basis for all reality, but also as the whole of reality itself, was Hegel's sole, lifelong philosophical goal. It took him some time to be able to formulate this project explicitly. This is linked to his intellectual development (see §2 above). He also considered various approaches to the realization and development of this project (see §3 above), but he never felt any need to question the project itself.

5 *The system:* Phenomenology of Spirit

The *Phenomenology of Spirit* (1807) is Hegel's most influential work. It serves as an introduction to his philosophical system by means of a history of the experience of consciousness. The *Phenomenology of Spirit* represents only one of a number of introductory attempts he made. In the Jena writings and system drafts, a discipline which Hegel calls 'logic' assumes this function. This logic is intended to fulfil its introductory function by raising our 'normal' thinking, which is characterized by its confinement to irreconcilable oppositions, to the level of 'speculation' – Hegel's term for philosophical thinking. Speculative thought is characterized by the knowledge of the reconcilability of oppositions and of the mechanisms of their coming about. That thinking, which by its insistence on oppositions simultaneously maintains their basic irresolvability, Hegel referred to at this time as 'reflection'. He regarded the elevation of this thinking to the position of speculation as a destruction of the structures which characterize reflection, and which together constitute the finiteness of reflection. 'Finiteness' of reflection or (used by Hegel as a synonym) of the understanding (*Verstand*) is initially a way of saying that thinking whose oppositions are irreconcilable moves within limits and must thus be regarded as finite. According to Hegel, it is now the task of logic to carry out the destruction of the finiteness of reflection or of the thinking of the understanding, thereby simultaneously leading to the standpoint of speculation or of the thinking of reason. Hegel sees the problem of a logic, which he understands as an introduction to philosophy, to be to carry out this destruction in such a way that not only the limitations of the thinking of the understanding and its preconditions are presented as mistakes and absurdities, but also that during this destructive process those structures become clear which guarantee a reasonable (that is, an intrinsic speculative) insight into the basic structures of reality.

Towards the end of his Jena period, Hegel abandoned the project of developing a logic as an introduction to his system of philosophy, and in its place presented a new discipline which he called the 'Science of the Experience of Consciousness' or 'Phenomenology of Spirit'. The declared goal of this discipline is twofold: on the one hand, it should destroy our supposedly natural picture of the world, and thus also our understanding of ourselves as the more or less consistent holders or subjects of this view, by demonstrating the contradictions which arise in our normal, complex view of the world. And second, it should thereby vindicate his ontological monism by demonstrating that our natural tendency to view the world as consisting of objects something which are both alien and different from us is not tenable. Instead we have to accept that in order to account for the real constitution of the world, and thus of objects and objectivity, we must presuppose, that we and the world represent a structural unity with the essential characteristic of being conscious of itself.

Hegel pursues this dual goal in a complex and ambitious thought-process, which attempts to combine and position within a comprehensive context a wide range of themes – historical, epistemological, psychological, meta-scientifical, ideological-critical, ethical, aesthetical and religio-philosophical. This whole thought-process is based on two convictions which govern Hegel's entire construction. (1) It is possible to conceive of all epistemic attitudes of a consciousness towards a material world as relations between a subject termed 'cognition' (*Wissen*) and an object termed 'truth' (*Wahrheit*). That which is presented as cognition or truth is in each case determined by the description which the consciousness is able to furnish of its epistemic situation and its object corresponding to this situation. (2) 'Knowledge' (*Erkenntnis*) can only be taken to be that epistemic relation between cognition (subject) and truth (object) in which

cognition and truth correspond with each other, which for Hegel is only the case if they are identical. A necessary, though not sufficient, condition for claiming this relationship of identity between cognition and truth is that what is regarded as cognition or as truth respectively is not formulated in a self-contradictory or inconsistent manner. For the Hegel of the *Phenomenology of Spirit*, and of the writings which were to follow, knowledge in the strict sense is thus really self-knowledge.

In characterizing the various epistemic attitudes of a consciousness to the world in the *Phenomenology of Spirit*, Hegel takes as his starting point something which he calls 'sense certainty'. He uses this term to describe an attitude which assumes that in order to know the true nature of reality we must rely on that which is sensually immediately present to us as a spatiotemporally given single object. Hegel demonstrates the untenability of this attitude by attempting to prove that in such an immediate reference to objects nothing true can be claimed of them. Moreover this immediate approach shows that any attempt to gain knowledge of what an object really is implies at the outset a different attitude towards objects. This attitude is determined by the assumption that what we are really dealing with if we refer to objects in order to know them is not the immediately given object, but the object of perception, which is characterized by Hegel as an entity defined through its qualities. According to Hegel, however, even this attitude is not tenable. Neither the perceiving consciousness, nor the object perceived, nor the relationship which is believed to exist between the two can be accepted in the manner in which they appear in this constellation: the subject, which aims to perceive the object of perception as that which it really is, can neither formulate a consistent concept of this object nor describe itself in unequivocal terms. The consciousness is thus led to a concept of an object which differentiates between what the object is in itself and what it appears to be. In order to differentiate in this manner, the consciousness must define itself as understanding, to which the inner constitution of the object in itself is disclosed as being constituted by its own laws, that is, by the laws of the understanding. Although, according to Hegel, this interpretation of the objective world through the cognizing subject also produces neither a truthful concept of the cognizing consciousness nor of the object in question, it none the less leads to the enforcement of an attitude according to which consciousness, when referring to an object, is referring to something which it is itself. The realization of this insight – that consciousness, when referring to objects, in reality relates to itself – converts consciousness into self-consciousness.

The various ways in which consciousness deals with itself and the objective manifestations corresponding with these ways as reason and spirit are comprehensively discussed by Hegel in the remainder of his *Phenomenology of Spirit*. It is in this context that he presents some of his most famous analyses, such as the account of the master–servant relationship, his critique of the Enlightenment and the French Revolution, his diagnosis of the strengths and weaknesses of the ancients' ideas of morality and ethical life and his theory of religion. The conclusion of the *Phenomenology of Spirit* forms what Hegel calls 'absolute knowledge'. Hegel characterizes this knowledge also as 'comprehending knowledge' (*begreifendes Wissen*), aiming thereby to highlight two ideas: (1) that this knowledge is only present when the subject of the knowledge knows itself to be identical *under every description* with the object of that knowledge. Comprehending knowledge therefore only occurs when the self knows itself to be 'in its otherness with itself', as Hegel puts it at the end of the *Phenomenology of Spirit*. He also aims to point out (2) that this type of identity of a subject with an object is that which constitutes the essence of that which he calls the 'Concept' (*Begriff*) of reason. The task of the *Science of Logic* is to develop this 'Concept' of reason in all its logical qualities. The goal of the *Phenomenology of Spirit*, the discipline which is to provide an introduction to logic, is achieved when it becomes evident to the consciousness that (Hegelian) truth only belongs to the (Hegelian) Concept.

But the *Phenomenology of Spirit* is not just an introduction to the system. From another point of view, Hegel describes the phenomenological process as 'self-fulfilling scepticism'. By means of this metaphor he attempts to establish a link to a subject closely connected with his critical assessment of his cultural and political environment, namely that of dichotomy (*Entzweiung*). For Hegel, the modern age is characterized by the fact that unity has disappeared from people's lives. The all-embracing unity of life can no longer be experienced, as people are no longer in a position to integrate the various aspects of their understanding of the world in a conflict-free context. So, for example, their moral convictions will force upon them a view of the world in which something like freedom and consequently something like the belief in the possibility to cause events based on free decisions occupies an irrefutable position. This view, based on moral convictions, stands in a conflicting and, finally, aporetic relationship to their scientific view of the world, which commits them to an understanding of the world in which there are no first causes or unconditioned facts, because each cause must itself be interpreted anew as an effect, whose

cause can only be seen as determined by previous circumstances. In this view of the world there is apparently no place for freedom. The conflict between various aspects of the understanding of the world, cited here by way of example, is for Hegel by no means singular; instead, it runs like a leitmotif through the modern conceptualizations of all spheres of life. He initially interprets it wholly in the spirit of Rousseau as a product of culture and civilization. This conflict is what separates a human being from itself, so that it continues to be denied a coherent image of the world. As a creature living in dichotomies, the modern person is an example of what Hegel calls the 'unhappy consciousness'.

Modern consciousness now attempts to solve this conflict by making each in turn of the conflicting views into the dominant attitude of its entire interpretation of the world. In this way, however, it can only achieve a one-sided interpretation of reality, which is just as incapable of doing justice to the true nature of reality as to the need of human consciousness to integrate all aspects of reality into its understanding of the world as a coherent unity. According to Hegel, it is in this situation that the need for philosophy arises. It is philosophy's task to destroy these one-sided total interpretations of consciousness and in this destruction to lay the foundation for the true complete interpretation of reality. The *Phenomenology of Spirit* describes this process of destruction and foundation-laying. The consciousness experiences it as a process of permanent destabilization of all the convictions on which it has always based its one-sided interpretations of the world. In this sceptical approach it is forced to doubt everything and to abandon all its supposed certainties. While the phenomenological process thus concedes a philosophical value to scepticism, in Hegel's understanding it simultaneously overcomes this scepticism by claiming a truth-revealing function for it. It is also Hegel's intention that the *Phenomenology of Spirit* should in this respect be understood as a treatise on the cathartic effect of philosophical scepticism.

Two questions have often been raised in connection with Hegel's conception of the *Phenomenology of Spirit* as an introduction to his 'System of Science', especially his logic. The first is whether Hegel does not assume in advance certain central theses of the discipline to which the *Phenomenology of Spirit* is intended to provide an introduction. This question draws attention to a methodological problem which originates from Hegel's assertion that the process of consciousness described in the *Phenomenology of Spirit* is not guided by any preconditions external to this process. This assertion seems difficult to square with certain manoeuvres which Hegel makes during the course of the *Phenomenology of Spirit*. The second question is of a more intrinsic nature and concerns the categorical apparatus employed by Hegel in the *Phenomenology of Spirit*. In this context, in particular his phenomenological conception of negation and identity as well as his concepts of knowledge and of cognition aroused critical interest from the very beginning.

It is difficult to determine exactly how Hegel himself later assessed the success of the *Phenomenology of Spirit* as an introduction to the point of view which is assumed at the beginning of his *Science of Logic*. On the one hand, he seems to have allotted it a certain value throughout his entire life, not only as a history of consciousness but also as an introduction. This is shown not only by the fact that he made arrangements for the publication of a second edition of the work immediately before his death, but also by later statements in the various editions of the *Science of Logic* and the *Encyclopedia of the Philosophical Sciences*. However, it is in precisely these statements that one finds Hegel expressing an increasingly critical attitude towards his project of a phenomenological introduction to the system. In this context it should also be recorded that by 1827 at the latest (that is, from the second edition of the *Encyclopedia of the Philosophical Sciences*) Hegel no longer has recourse to a version of phenomenology as 'a more detailed introduction, in order to explain and lead to the meaning and the point of view which is here allotted to logic', but for this purpose uses instead a discussion which deals with three different 'attitudes of thought to objectivity'.

6 *The system:* Science of Logic

The real centre of the Hegelian system is the discipline he described as 'Logic'. It contains his doctrine of the categories, to use traditional terminology (see CATEGORIES). Hegel dedicated his most comprehensive and complex work to this discipline, the *Science of Logic* (1812–16), later adding a much shorter version within the framework of the *Encyclopedia of the Philosophical Sciences*.

The starting point of the *Logic* is the insight, justified in Hegel's view by the result of the *Phenomenology of Spirit*, (1) that all true knowledge is knowledge of oneself, and (2) that the subject of this knowledge, that is to say, that which knows about itself, is reason. Because Hegel – following Schelling – only considers that to be real which can also be known, he concludes from the results of the *Phenomenology of Spirit* that only reason is real. He thinks of this reason as, internally, an extremely complex entity. Hegel now distinguishes between the 'Concept' of reason and the process of its realization. The object of the *Science of Logic* is the conceptual, that is to say, for Hegel, the logical

development of this Concept. Since this Concept is the Concept of that which alone is real, Hegel can maintain that his *Science of Logic* takes the place of traditional metaphysics, which concerned itself with the elucidation of the basic ways in which we can think of reality.

Since the object whose Concept is to be logically discussed is reason, understood to be the sum of reality, the Concept of reason must include not only those aspects which account for reason's character of reality or of being, but also those aspects which do justice to the peculiar character of reason as thinking. Hegel calls both these aspects 'Determinations of the Concept' (*Begriffsbestimmungen*). Those aspects of the Concept of reason which take into account its character of being are developed by Hegel in the section 'Objective Logic' in the *Science of Logic.* He presents those aspects which are intended to do justice to its thinking character in the section called 'Subjective Logic'. He further subdivides 'Objective Logic' into 'Logic of Being' and 'Logic of Essence'.

In his 'Objective Logic', Hegel tries to show how it is possible to generate from very simple, so-called 'immediate' determinations such as 'Being', 'Nothing' and 'Becoming' other categories of quality and quantity as well as relational and modal determinations, such as 'Cause-Effect', 'Substance-Accidence' and 'Existence', 'Necessity' and the like. As in the 'Subjective Logic', the basic strategy here for the creation of categories or determinations of the Concept, assumes that (1) for every category there is an opposing one which upon closer analysis reveals itself to be its true meaning, and that (2) for every two categories opposing each other in this manner there is a third category whose meaning is determined by that which makes the opposing categories compatible. Hegel considers these two assumptions justified because only they can lead to what in his eyes is a complete and non-contingent system of categories. Hegel himself, however, did very little to make their exact sense clear, although he uses them with great skill. Immediately after his death this led to a confused and still inconclusive discussion regarding their interpretation. Many judgments concerning the worth or worthlessness of Hegel's philosophy are linked to this discussion, which has taken its place in the annals of Hegel research as a discussion concerning the meaning, significance and value of the so-called 'dialectical method'. (Hegel himself preferred 'speculative method'.)

In particular, Hegel's claims about the truth-generating function of contradiction have played a major role in the discussion of the 'dialectical method' described in the *Science of Logic.* Though highly praised by Hegel himself, his doctrine of the nature and methodological merits of contradiction has proved to be inaccessible and obscure. This may have been caused in part by Hegel's extremely concise and provocative formulations of this methodical maxim. The reader is reminded in this context not only of the succinct formulation which he chose to defend on the occasion of his Jena Habilitation – 'contradiction is the rule of truth, non-contradiction the rule of falsehood' – but also of his provocative version of the principle of contradiction, according to which 'everything is inherently contradictory'. The difficulties associated with the comprehension of the Hegelian conception of contradiction have perforce a link with his particular unconventional concept of contradiction. Two points are particularly important, in that they differentiate his concept from the classical concept of contradiction of traditional logic. (1) A contradiction between two propositions cannot be confirmed solely on the basis of their ascription to a single subject of two contradictory predicates; it is also necessary to take into account the meaning of the subject of these propositions. If the contradictory predicates cannot meaningfully be attributed to the subject, then no contradiction arises. 'Legible' and 'illegible' are predicates which will only lead to contradiction if attributed to texts, but not, for example, to bananas. For Hegel, this means among other things that the relation of contradiction is dependent on the context. (2) Hegel thinks of contradictions as analogous to positive and negative determinations, which neutralize each other but without making that whose neutralizing determinations they are into a contradictory concept which has absolutely no meaning, which therefore means nothing (the Kantian 'Nihil negativum'). Rather, the way in which positive and negative determinations neutralize each other tells us something informative about the object to which the neutralizing determinations apply. For example, possession of Euro 100 neutralizes a debt of Euro 100, without thereby making the concept of property a contradictory concept. Instead, the way in which this neutralization takes place makes clear that the concept 'property' means something which must be thought of as of a quantifiable size. For Hegel this is a consequence of 'the logical principle that what is self-contradictory does not dissolve itself into a nullity, into abstract nothingness, but essentially only into the negation of its *particular* content'. Whether these two convictions are sufficient to justify Hegel's thesis that contradictions play a 'positive' role in cognition procedures is rightly controversial.

Hegel's 'Subjective Logic', the second part of the *Science of Logic*, contains not only his so-called 'speculative' interpretation of the objects of traditional

logic, that is, his own doctrine of concepts, judgments and syllogisms, but above all his theory of the 'Concept'. This theory is deeply rooted in Hegel's critique of traditional metaphysics, and is thus most easily comprehended when placed in that context. He presents this critique most tellingly in the third edition of the *Encyclopedia of the Philosophical Sciences*. His starting point here is the claim that what matters in philosophy, and what philosophy aims at, is the 'scientific recognition of truth'. This means among other things that philosophy is concerned with the recognition of 'what objects really are'. According to Hegel, the question of what objects really are has been approached in philosophy from a variety of angles, but all the different modes in which the question has been answered to date are unacceptable because they are based on false premises. Traditional metaphysics is one of the ways of approaching the question of what objects really are. Hegel characterizes this approach as 'the *unbiased* method', which is motivated by the assumption that 'through *thinking the truth becomes known*, what objects really are is brought to one's consciousness'. In contrast to other philosophical approaches that deal with the question posed, metaphysics, according to Hegel, is in principle certainly capable of contributing to the cognition of what things in truth are, because it starts from the correct assumption that 'the determinations of thought' are to be seen as 'the fundamental determinations of things'. But traditional metaphysics has not made a significant contribution to the cognition of truth, because it was only able to transform its correct initial assumption in a systematically erroneous manner.

According to Hegel, the crucial weakness of traditional metaphysics is to use the form of judgment *in an unreflective manner*, and this shows itself in various ways. First it shows in the unfounded assumption of traditional metaphysics that judgments provide a particular and direct insight into the constitution of reality or that which really exists. In Hegel's view this unfounded assumption has two consequences: the first is that it tends without reason to favour a particular ontological model of reality because it regards the subject-predicate form as the standard form of the judgment; the second consequence, in Hegel's view incomparably more problematic, consists of the unfounded tendency of traditional metaphysics to conclude from the unquestioned and assumed correspondence between the form of judgment and constitution of reality that one can express by means of judgments what objects really are. Hegel does not find problematic the assumption contained in this conviction that one can make judgments concerning objects. He believes that the problem lies rather in the fact that one can assume *without examination* that 'the form of the judgment could be the form of truth'. In Hegel's view, however, such an examination is essential because the traditional understanding of subject and predicate does not justify the assertion that a subject-predicate judgment actually contributes something to the determination of a real object. An additional problem lies in the fact that the unconsidered use of the form of judgment has led traditional metaphysics erroneously to use a 'natural' interpretation of the concepts of subject and predicate. The consequence of this interpretation is that judgments of the subject-predicate form can lay no claim to 'truth'.

Hegel's chief criticism of traditional metaphysics therefore lies in the lack of clarity associated with its interpretation of the form of the judgment. In particular he rejects its tendency to interpret the judgment 'naturally', which for him means to encourage a subjectivist interpretation of the judgment built on the concept of representation. Such a subjectivist interpretation cannot show how to guarantee for the judgment some sort of claim to truth or recognition of what something really is. Therefore the subjectivist metaphysical interpretation of the judgment is problematic at the very outset. Moreover, it becomes downright dangerous when one considers its ontological implications, for it leads erroneously to the assumption that the objects corresponding to the subject-concepts of the judgment are to be thought of as substances to which are attributed the characteristics described by the predicate-concepts. The unreflective subjectivist interpretation implies or at least suggests what may be called a substance-ontology, according to which substances which are independent of each other are taken as the fundamental entities of reality, determined predicatively by accidental characteristics which are applicable or not applicable to them. It is this commitment to a substance-ontology which Hegel critically imputes to traditional metaphysics. From this criticism, he deduces that it is first necessary to reach an agreement as to what the object really is before one can adequately assess the function and the achievement of the judgment in the context of knowledge. To reach this agreement is the task of the Logic of the Concept.

The starting point of Hegel's theory of the Concept is the assumption which he imputes to traditional metaphysics as an insight which is in principle correct. This was the insight that only through thinking can one recognize what something really is. Since in Hegel's view thinking is concerned not with intuitions or representations, but with concepts, he identifies that which something in truth or really is with its Concept. Because of this identification, talk of the Concept acquires

an ontological connotation. Hegelian Concepts must not be confused with the so-called general concepts of traditional logic. They are difficult to understand precisely and are characterized by the fact that they are (1) non-sensible – which means that they are a particular type of thought-object – and that they are (2) something objective as opposed to subjective. Regarded as these objective thoughts, these Concepts are determined in the sense that in them different relations of determinations of the Concept are to be encountered which occur as determinations of thinking or of thought (*Denkbestimmungen*). These determinations of thought can themselves be regarded as a kind of predicative characteristic. They make up the multitude of all those determinations on the basis of which the Concept of an object can be seen as completely fixed.

Now, in Hegel's view, not everything has a Concept which in one sense or another is ordinarily thought of as an object. A (Hegelian) Concept is only allotted to objects which can be thought of on the model of an organism. Hegel thus maintains that one can only regard those objects as real or as existing in truth for which there is a Concept which can be interpreted on the organic model. If, then, the 'scientific recognition of truth' consists in recognizing the Concept of something, and if a Concept is always a Concept of a organic-type object, then the question arises how one should conceive of such a Concept. For Hegel it is clear that in his concept of a Concept, he must include everything needed to describe an organism. This includes first of all what Hegel calls the subjective Concept, which one can best regard as the sum of all characteristics whose realization represents an organic-type object. For Hegel, in the case of the concept of reason, whose Concept the *Science of Logic* elaborates, these characteristics are exclusively logical data which can be presented in the form of determinations of concepts, judgments and syllogisms. Furthermore, Hegel's Concept must include the element of objectivity. 'Objectivity' here means more or less the same as reality or the state of being an object and suggests the fact that it is part of the Concept of an organism to realize itself. Since, however, Hegel holds that there is ultimately only one object which really exists, namely reason, the Concept of this object must include a characteristic which is exclusively applicable to itself. This characteristic must permit the justification of the claim that in reality there is only one Concept and therefore also only one object. Hegel calls this characteristic 'subjectivity'.

Although it is easy to see that the term 'subjectivity' describes a central element of Hegel's logical theory, it is very difficult to shed light upon its meaning and function therein. It is relatively obvious only that Hegel attributes the characteristic of subjectivity not just to his Concept, but also to entities such as 'I', 'self-consciousness' and 'spirit'. We are therefore on safe ground if we assume that the subjectivity which is to be attributed to the Concept is precisely that which is also attributed to the I, self-consciousness or spirit and which distinguishes them from other types of organism. The ground becomes more dangerous when it is a matter of stating what subjectivity actually means. This is not merely because Hegel distinguishes between different types of subjectivity, but also because the subjectivity which is constitutive of the Concept is tied to conditions which are difficult to state with any precision. In general it seems to be correct to say that subjectivity occurs when something recognizes itself as being identical with something else. If we follow the *Science of Logic*, then this relationship of identity known as 'subjectivity' can only be established between entities which themselves can be thought of as being particular complexes of relations of similar elements or moments. Subjectivity in this sense is thus intended to describe a certain form of self-reference or self-relationship. According to Hegel, there should be only one entity to which the term 'subjectivity' can be attributed as a characteristic in the sense which has just been explained – the Hegelian 'Idea'. He says of it, 'The unity of the Idea is subjectivity'. This Idea now forms the end of the *Science of Logic*, because through it the Concept of reason has been completely explicated. He also describes this Idea as the absolute method, for it is not only the result, that is, the Concept which comprehends all his moments, but also the complete and systematically generated series of these moments.

The results of the Logic of the Concept represent the justification for Hegel's belief that, apart from a system of logic, a complete system of philosophy must include a so-called 'real philosophy', which is divided into a philosophy of nature and a philosophy of spirit. Hegel undertakes this justification within the framework of the exposition of what characterizes the fully developed (Hegelian) Concept. This exposition only becomes comprehensible if one remembers that Hegel is a supporter of the organological paradigm in metaphysics, according to which that which really is must be regarded as a particular type of organism. Hegel describes the type of organism relevant to his metaphysics as an object which has realized or objectivized its Concept in such a way that it comprehends itself as the objectivization of this Concept of itself. On the basis of this conception, Hegel now develops the following consideration: the (Hegelian) Concept is something which is to be regarded as a unity of

(in some ways incompatible) determinations of the Concept. Among these determinations also belong, as Hegel believes he can show, that of objectivity. By this he means that it is a part of the nature of a Concept to become objective, to manifest itself as an object. Now, the only object which is an adequate realization of the Concept is the one to which what Hegel calls 'subjectivity' can be attributed. 'Subjectivity' is the name of a relational characteristic which is present when something *knows* itself to be identical with something else. For Hegel, it follows from these stipulations that subjectivity can only be attributed to the object which knows itself to be identical with its Concept. To produce this knowledge is therefore a demand inherent in the nature of the Concept. Since it is the sole task of the *Science of Logic* to exhibit the Concept of reason, and since this Concept contains the demand for the production of a form of knowledge which can only be acquired when (1) the Concept objectivizes itself, that is, becomes an object, and (2) this object comprehends itself as being identical with its Concept, then it is already a demand inherent in the Concept of reason that reason should be discussed (1) from under the point of view of its objectivity or as an object, and (2) under the aspect of its known identity with its Concept. The first of these topics is the subject of a philosophy of nature; the second that of a philosophy of spirit.

7 The system: philosophy of nature

Hegel's philosophy of nature is an attempt to explain how it is possible that we can recognize nature as a complex whole standing under a set of laws. He thereby takes up the question, important in particular to both Kant and Schelling, of which epistemological and ontological preconditions underlie our conviction that nature can be known. Although Hegel had thought about the problems of a philosophy of nature since his time in Frankfurt, and although he produced several versions of a philosophy of nature during his Jena period, he only published an outline of this part of his system once, quite late, in his *Encyclopedia of the Philosophical Sciences*. Hegel's philosophy of nature is of interest mainly in three respects. The first concerns the way in which he transforms his logical theory into an interpretation of natural phenomena. The second relates to the question of how far Hegel's conceptions in the field of the philosophy of nature take into account the scientific theories current at the time. Finally, the third leads to the question of what we should make of Hegel's approach to a philosophy of nature within the framework of present-day philosophy of science. Since the philosophy of nature is that part of the Hegelian system which is traditionally regarded with the greatest suspicion and which for this reason has received the least scholarly attention, the assessment of the second and third aspects of this philosophy of nature has so far produced very few uncontroversial results.

As far as the construction of a philosophy of nature according to the requirements of the logical theory of the Concept is concerned, Hegel assumes in accordance with his organological conception of reason that we should think of nature '*in itself* as a living whole'. This living whole has to be conceived of primarily under three different determinations, which reproduce to a certain extent the central characteristics of the Concept of reason as developed by the logical process. According to the first of these determinations, nature is to be considered as a whole defined by space, time, matter and movement. This way of looking at nature makes it the object of what Hegel calls 'mechanics'. According to Hegelian mechanics, space, time, matter and movement, their characteristics and the laws of nature which describe their relationship are generated by the formal structural moments of the (Hegelian) Concept. The utilization of such a 'conceptual' procedure to gain and secure scientific results was never seen by Hegel himself as a direct alternative procedure to empirical scientific research. On the contrary, he was of the opinion that (for instance, by means of his philosophical mechanics) he only makes explicit, and secures a rational foundation for, the conceptual elements which are implicitly contained in every scientific mechanical theory that acquires its data 'from experience and then applies a mathematical treatment'.

According to Hegel, his philosophical mechanics leads to the insight that we must think of the whole of physical nature as 'qualified matter', that is, as a totality of bodies with physical characteristics. This provides the second main determination by which nature is to be comprehended. Hegel ascribes to this way of comprehending nature a discipline which he calls 'physics', including under this heading everything which can in any way be linked with the material status of a body. Accordingly, from phenomena like specific weight, through those like sound, warmth, shape, electricity and magnetism, to the chemical reactions of substances, everything is described as being a consequence of and following from the constitution of the (Hegelian) Concept. He also adds theses concerning the nature of light and a doctrine concerning the elements earth, fire, water and air. It was this part of Hegel's philosophy of nature in particular which drove Hans Scholz, among others, to the following crushing judgment: 'Hegel's philosophy of nature is an experiment which set the philosophy of nature

back several centuries instead of furthering its cause, returning it to the stage it had reached at about the time of Paracelsus'. Whether this dictum has substance, however, depends very much on what conception of nature and science one favours.

The third part of Hegel's philosophy of nature consists of the so-called 'organic physics' or 'organics'. In this section the characteristic of subjectivity, familiar from his logical theory, is the determination under which nature is to be regarded. Since in the context of the philosophy of nature, Hegel interprets subjectivity as an essential characteristic of organic life, this section of his philosophy of nature is concerned with nature as a hierarchy of organisms or as an 'organic system'. He distinguishes between three forms of organic life which are exemplified in three types of organism: the general form, which is represented by the geological organism, the particular, which is realized in vegetation, and the individual, which finds its expression in animal organisms. He regards these forms as hierarchically ordered by increasing degree of complexity. In some ways Hegel thematizes relations and conditions of dependence: just as vegetable life-forms presuppose geological structures and processes, so animal organisms presuppose a fully developed plant world. Hegel links this last part of his philosophy of nature to his philosophy of spirit by means of an analysis of the phenomenon of the death of an individual natural being. Here the leading idea is that although through death all natural determinations of the individual are removed, so that we can speak of the 'death of the natural element', none the less death does not annihilate the principle of life, that which is responsible for the essential unity of animal organization and which Hegel calls the 'soul'. Since Hegel interprets the soul as a form of spirit, and since according to his conception the soul is not destroyed by death, he can now postulate the reality of spirit independently of natural determinations as the result of his philosophy of nature, and investigate this reality in its various forms within the framework of a philosophy of spirit.

The question whether Hegel's philosophy of nature integrates in a relatively informed manner the state of science during his lifetime has provoked a number of fairly controversial answers, as has the question whether his approach can still provide any promising perspectives which are relevant today. During the nineteenth century, Hegel's philosophy of nature was broadly considered scandalous by the majority of scientists, an attitude which contributed in no small measure to the discrediting of his philosophy as a whole. This assessment also meant that Hegel's philosophy of nature has never really been taken seriously again. Since 1970, however, the situation has changed somewhat. Starting from and relying on recent investigations in the history of science regarding the development and state of the sciences during the early nineteenth century, increasing numbers of scholars are inclining towards the view that Hegel was indeed much more familiar with the science of his time and its problems than was generally believed during the nineteenth and most of the twentieth century. It seems advisable at present to refrain from passing final judgment on this matter. The same cannot, however, be said with regard to the present relevance. Here one cannot ignore the fact that Hegel's theses concerning philosophy of nature are, quite simply, meaningless for present-day scientific theory.

8 The system: philosophy of spirit

Hegel's philosophy of spirit is divided into a theory of subjective, objective and absolute spirit. The philosophy of subjective spirit contains Hegel's philosophical psychology; his philosophy of objective spirit is devoted to his theory of law and politics and his conception of world history; and his philosophy of absolute spirit presents his theory of art, religion and philosophy. Hegel presented his philosophy of subjective spirit and in particular his philosophy of absolute spirit to a wider public only in outline in a few paragraphs of the *Encyclopedia of the Philosophical Sciences*. He presented his philosophy of objective spirit not only in the *Encyclopedia*, but also in detail in a work which was already highly regarded during his lifetime, *Natural Law and Politics in Outline: The Principles of the Philosophy of Right* (1821). In this part of his system Hegel again relies on the principle developed in his logical theory that something – here the entity called 'spirit' – must experience a process of realization in order to be able to recognize its truth, or what it is.

The philosophy of subjective spirit contains an anthropology, a phenomenology of spirit and a psychology. In these sections Hegel describes and analyses all the phenomena that influence the somatic, psychophysical and mental characteristics, conditions, processes and activities of the individual. The gamut of subjects he covers runs from the natural qualities of the individual, expressed in temperament, character and physiognomy, via sensibility, feeling, awareness and desire, to self-awareness, intuition, representation, thinking and wanting. Here one finds Hegel's theory of language acquisition, of practical feeling, of the achievements and function of imagination, his defence of the life-preserving power of habit, his solution of the mind–body problem, his understanding of the origin and treatment of mental illnesses and many other subjects. In these analyses Hegel's aim is to replace

the 'ordinary approach' of empirical psychology with a 'philosophical perspective' towards psychological phenomena. The dominant characteristic of this philosophical attitude, it is claimed, is that it permits an interpretation of the subject of psychic processes as the product of psychic activity and not as an object to be thought of as a substance possessing certain powers and capacities which are its characteristics.

While the philosophy of subjective spirit really only attracted attention up to the middle of the nineteenth century, Hegel's philosophy of objective spirit, in other words his theory of law and politics, received a great deal of attention during the nineteenth and especially the twentieth century. This was not only because of the theory's great importance for the Marxist and other anti-liberalistic social theories (see MARX, K.; MARXISM, WESTERN). It has also repeatedly been the object of violent controversy, especially because of its political implications. In all its versions, Hegel's political philosophy rests on three main convictions which he cherished from his early years and held for the rest of his life. The first is that every modern philosophy of law and politics must incorporate the conception of freedom which was central to the European Enlightenment, and in particular to that of Germany (see ENLIGHTENMENT, CONTINENTAL). The second is that, especially in the case of modern political philosophy, the insight that the whole takes priority over its separate parts, an insight formulated by ARISTOTLE in his *Politics*, must be maintained and brought up to date. Finally, the third conviction consists in an application of the principle which shapes Hegel's whole philosophical enterprise, namely, that political philosophy must play its part in the confirmation of the thesis that only reason is real. Hegel attempts to do justice to these three convictions within the framework of his theory of objective spirit by (1) introducing an extravagant conception of freedom, (2) identifying the whole of Aristotle with the phenomenon which he calls 'ethical life' and (3) declaring this phenomenon called 'ethical life' to be the 'reality of reason'.

Hegel fulfils his self-imposed demand for the integration of freedom by making the conception of free will the fundamental concept of his philosophy of the objective spirit; this is where his characteristic conception of freedom comes into play. According to Hegel, a will is free not because it can choose its ends from a virtually limitless number of objective alternatives; the truly free will is the will which only determines itself. For Hegel, self-determination means to refer willingly to oneself, that is, to will oneself. Thus he thinks of freedom as a case of self-reference and in this way assimilates it into his concept of cognition, which is also based on the idea of self-reference (see §5 above). This assimilation is utterly intentional on Hegel's part, because it gives him the opportunity to interpret the process of the systematic unfolding of the various determinations of the will not only as different ways of the realization of free will but also as a process of cognition (see FREEDOM AND LIBERTY; FREE WILL).

Against this background, Hegel first develops his theories of law and morality, which derive all legal relationships and the obligatory character of moral acts from the concept of free will. In his theory of law, Hegel makes his contribution to the discussion of the philosophical foundations of civil and criminal law. His basic thesis is that property, the acquisition and use of which is a presupposition for being able to act freely, is the necessary condition of law in all its different variations. In his theory of morality, Hegel discusses the moral behaviour of autonomous subjects under the aspect of the gaining of moral standpoints for the purpose of judging actions and of the conversion of moral goals into actions. According to Hegel, however, legal relationships and moral standards are *founded* in social institutions. He thinks of these institutions as forms of what he calls 'ethical life' (*Sittlichkeit*). In Hegel's language, ethical life as the basis for the possibility of law and morality is the truth of free will, that which free will really is. Since it is a characteristic of the truth of free will to be real, it follows that, for Hegel, ethical life is also the reality of free will. This reality is thus the 'presupposed whole', without reference to which the discussion of law and morality makes no sense at all. This thesis of the function of real ethical life as the basis for law and morality is intended to account for the Aristotelian maxim of the primacy of the whole in political philosophy.

For Hegel, ethical life appears in three institutional forms: family, bourgeois society and the state. The theory of the family contains his thoughts on the ethical function of marriage, his justification of monogamy, his views on family property and the laws of inheritance and his maxims for bringing up children. The theory of bourgeois society became well-known and influential, above all because of Hegel's diagnosis of the difficulties which will arise within a society based solely on economic interests and elementary needs of its individual members. This diagnosis is grounded in Hegel's analyses of a society founded solely on economic relationships. They owe much to the works on political economy by Adam Smith, J.P. Say and David Ricardo, to whom Hegel often explicitly refers. According to Hegel, a bourgeois society considered as an economic community is defined by the fact that in it people can satisfy their needs through labour. The

manifold nature of these needs means that they can only be satisfied by division of labour within the society. This leads economic subjects to join together into estates (*Stände*) and corporations whose members each undertake specific tasks with regard to the socially organized satisfaction of their needs. Hegel recognizes three estates: the peasant estate, which he calls the 'substantial estate'; the tradesmen's estate, among which he includes craftsmen, manufacturers and traders; and what he calls the 'general estate', whose members fulfil judicial and policing functions. Corporations are formed mainly in the tradesmen's estate. Although this entire realm of bourgeois society organized along these lines does involve legal restrictions, and is regulated by a civil and criminal legal code, it none the less cannot remain indefinitely stable. For it is not possible to prevent the polarization of the poor majority and the rich minority which leads to overpopulation, so that eventually the entire social wealth will not suffice to satisfy even the most elementary needs of all. The consequences are colonization and the formation of the 'proletariat'. Both will tend to destroy this bourgeois society.

If one follows Hegel's arguments, bourgeois society can only avoid this fate if its members act not according to their own particular interests and needs, but recognize the state as their 'general purpose', and direct all their activities to maintaining it (see STATE, THE). Hegel thinks of the state as a constitutional monarchy with division of power. For Hegel, the constitution of a state is in no sense the product of some constitution-creating institution or the work of individual persons. It is 'absolutely essential that the constitution, although the product of past history, *should not be seen as a finished entity*'. A constitution is rather the manifestation of the spirit of a people, created during the course of history through their customs and traditions. This view permits Hegel to maintain on the one hand that each people has the constitution 'which is appropriate to it and fits it', and on the other to insist that there is not much leeway for the modification of constitutions. The constitutional form of a reasonably organized state must be a monarchy because its characteristic individuality can only be appropriately represented by a concrete individual to whom as a person the sovereign acts of the state can be attributed. Hegel also favours a hereditary monarchy, since he sees the process of determining a person as monarch by virtue of its origin as the method which is least dependent upon arbitrary decisions. Hegel's theory of the powers of the state (*Staatsgewalten*) recognizes, in addition to the princely power (*fürstliche Gewalt*) which represents the instance of ultimate decision-making within the constitutional framework, the governmental power (*Regierungsgewalt*) and the legislative power (*gesetzgebende Gewalt*). It is the task of the governmental power, which for Hegel also includes the judicial power, to pursue the general interests of the state, ensure the maintenance of right and enforce the laws. The legislative power is responsible for the 'further determination' of the constitution and laws. It is executed by an assembly of the estates which is divided into two chambers. The first chamber consists of a certain group of powerful landowners chosen by virtue of their birth; the second chamber comprises representatives of the corporate associations of the bourgeois society, who are sent to the assembly by their various corporations. Thus in Hegel's model state, both chambers are constituted without the direct political involvement of the population. Hegel's theory of the state provoked considerable controversy, particularly during his own time, because of its resolute defence of the hereditary monarchy and its strongly anti-democratic characteristics in all questions concerning the political representation of the citizens of the state. It was this section of his political philosophy in particular which, as early as the mid-nineteenth century, gave rise to the statement that Hegel was the philosopher of the Prussian state.

Hegel forges the link to his theory of the spirit, which contains his political philosophy, by interpreting what he calls 'ethical life' as the 'spirit of a people'. This allows him to elaborate his conception of history on the one hand and on the other to introduce his theory of the absolute spirit. The philosophy of history is introduced by the idea that ethical life as the reality of free will takes on different forms for different peoples. These forms differ from each other in the degree to which the different institutions of ethical life are actually developed. Now, Hegel believes that this development has taken place during the course of a historical process which he calls 'world history' (see HISTORY, PHILOSOPHY OF). This process of world history, which he sees as 'progress in the consciousness of freedom', can be divided into four distinct epochs, which correspond to four 'empires of world history'. Hegel describes this process of world history as beginning with the 'Oriental Empire', which is followed by the 'Greek' and then by the 'Roman' empires. The process is brought to a conclusion by the 'Germanic Empire'. This empire is not to be identified with Germany alone. It includes all central European Christian nations, even Great Britain. According to Hegel, the 'Germanic peoples are given the task of accomplishing the principle of the unity of divine and human nature, of reconciling . . . objective truth and freedom'. Hegel now interprets this reconciliation as the conclusion of the process of the self-recognition

of reason. The result of this process consists of the insight that reason *knows itself* to be the whole of reality. Thus Hegel links the theory of the objective spirit with his metaphysics of reason and can now concentrate on the various aspects of this self-knowledge of reason as a theory of absolute spirit.

Hegel's philosophy of absolute spirit contains his philosophy of art, his philosophy of religion and his theory of philosophy. Although from his very beginnings all these subjects had a fixed place in Hegel's attempts at a system, and although his philosophies of art and religion were to become very influential (the one in the history of art and the theory of aesthetics and the other in theology), none the less these sections of Hegel's philosophy are relatively little elaborated in the works published by Hegel himself. Apart from a few sketch-like hints in his first work, *Difference between the Systems of Fichte and Schelling* (see §3 above), and the two final chapters of the *Phenomenology of Spirit*, Hegel devoted only a few paragraphs to these themes at the end of the *Encyclopedia of Philosophical Sciences*. We can gather from these paragraphs that there are three different ways or modes in which reason, cognizing itself, relates to itself; these are manifested in art, religion and philosophy. They differ from each other in the way in which in each of these ways reason cognizes itself. In art, reason relates to itself *intuitively* or, as Hegel says, *cognizes itself immediately*, while in religion this cognizing relationship with itself realizes itself in the form of *representation*, which is linked with the sublation of the immediacy of knowledge. In philosophy, the self-reference of reason is accounted for in the mode of *cognition*. The theory of epistemic modes which underpins this functional analysis of art, religion and philosophy, though obviously relying on the results of the Hegelian theory of the subjective spirit, none the less contains a number of difficulties which are hard to unravel.

Against this background of different forms of cognition, Hegel first reveals his theory of art in the form of a theory of styles of art (*Kunstformen*) and of individual arts (*Kunstarten*). He recognizes three different styles of art, which he calls symbolic, classical and romantic. They differ from each other in their various means of expressing the distinguishing characteristics of the spiritual, which belong to the sensible and therefore to the intuitive manifestations which reason gives itself. These styles themselves are characterized by the ways in which a spiritual content presents itself as the meaning of a sensible object. The symbolic style of art is thus the one in which the relationship between meaning and sensible appearance is relatively contingent, since it only arises through a randomly chosen attribute. By way of example Hegel takes the lion, which symbolizes strength. In the classical style of art the sensible appearance expresses adequately what it is intended to signify. For Hegel, the human figure serves as a paradigm for this adequate representation of the spiritual, especially in the way in which it is represented in sculpture and painting. Finally, the romantic style of art takes as its subject the representation of the 'self-conscious inwardness' of the spirit. In it, the emotional world of the subject is expressed by reference to sensible characteristics. Hegel interprets the various individual arts as realizations of styles of art in various materials. Although each individual art can present itself in each style of art, there is for each individual art an ideal style, which he calls its basic type. The first individual art which Hegel discusses is architecture. Its task is to deal with non-organic nature in an artistic manner. Its basic type is the symbolic style of art. The second individual art is sculpture, the basic type of which is the classical style. Sculpture aims to transform non-organic nature into the physical form of the human body. The remaining individual arts are painting, music and poetry, whose basic type is represented by the romantic style of art. Painting marks the beginning of the separation of the direct processing of natural materials and thus a certain intellectualization of matter, which makes it capable of representing feelings, emotions, etc. Music is the romantic style of art *par excellence*. Its material is sound, which is matter only in a figurative sense and is therefore particularly suitable for the representation of even the most fleeting affects. Finally poetry, the last of the romantic arts, has as its material only signs, which here play no part as material entities but instead are bearers of meaning. These meanings refer to the realm of imagination and other spiritual content, so that in poetry a spiritual content can be presented in a manner appropriate to its spirituality. Hegel could not resist the temptation to use his theory of individual arts and styles of art as a model for the interpretation of the history of the development of art. His historicizing of individual arts and styles of art played a significant role in making the concept of an epoch an important tool in the history of art.

In the philosophy of religion Hegel holds that only in Christianity are the conditions fulfilled which are characteristic of the representational self-cognition of reason. Philosophy of religion has as its subject not only God, but also religion itself, and for Hegel that means the way in which God is present in the religious consciousness. By this characterization he aims to distinguish philosophy of religion from the traditional *theologia naturalis*. On the basis of the two components which make up its nature, the philosophy of religion attempts in the first instance to characterize more closely the concept of God and the various kinds of religious consciousness

which Hegel takes to be feeling, intuition and representation. This will be found in the first part of the philosophy of religion, which thematizes the 'concept of religion'. The second part of the philosophy of religion discusses what Hegel calls 'determinate religion'. Here, he is concerned with something resembling a phenomenology of religions, the exposition of their various forms of appearance and objectivizations. This exposition starts with so-called natural religion, which according to Hegel assumes three forms: the religion of magic, the religion of substantiality and the religion of abstract subjectivity. The specific characteristic of natural religion is that it thinks of God in direct unity with nature. Natural religion finds its historical concept in the Oriental religions. Hegel regards the 'religions of spiritual individuality' as a second stage; these assume the forms of the religion of sublimity, the religion of beauty and the religion of teleology. At this stage, God is regarded as the primary spiritual being, which is not only nature but which also rules over and determines nature. Hegel puts the Jewish, Greek and Roman religions in this category. Finally, the third stage represents the 'perfect religion', to the discussion of which he devotes the third section of his philosophy of religion. In it, God is presented as He in reality is, namely the 'infinite, absolute end in itself'. To the religious consciousness, the God of the perfect religion appears in the trinitarian form as the unity of the Father, Son and Holy Ghost. According to Hegel, this idea of religion was first realized adequately in Christianity. Hegel's philosophy of religion greatly influenced theological discussions and points of view. None the less, it was not without its critics, for whom it represented a theory which, as, for example, R. Haym claimed in the last century, contributed to the dissolution of the Godly in reason and of Piety in knowledge.

As far as philosophy is concerned, Hegel maintains that its distinguishing mode of knowledge, namely cognition, is present when something is seen to be necessary. Since reason within the sphere of the absolute spirit relates only to itself, the achievement of the cognitive reference of reason to itself lies in the fact that it understands the progress of its realization in logic, nature and spirit as a necessary process. Philosophy is the representation of this process in its necessity. This philosophical process also has its appearance in time in the form of the history of philosophy. For Hegel, the history of philosophy presents itself as a historical succession of philosophical positions in which in each case one of the essential characteristics of (Hegelian) reason is made the principle of a philosophical interpretation of the world in a one-sided and distorted way that is characteristic of its time. He sees the existence of political freedom as a necessary precondition for a philosophical interpretation of the world. Only in societies in which free constitutions exist can philosophical thought develop. Since, he claims, the concepts of freedom and constitution only arose as the products of Greek (that is, Occidental) thought, philosophical discourse is really a specifically Western achievement. He therefore absolutely refuses to ascribe any philosophically relevant intellectual achievements to the Oriental world, the principle proponents of which are in his view China and India. All the doctrines of wisdom of the Orient can at most be accepted as codifications of religious ideas. If, for a Westerner, some of these doctrines none the less seem to express a philosophical thought, this is because they confuse the abstract generality of Oriental religious ideas with the generality which is applicable to the thoughts of reason engaged in thinking itself. Hegel divides Western philosophy into two main periods: Greek and Germanic philosophy. Up to a certain point, Greek philosophy also includes Roman, and Germanic philosophy includes not only German philosophy but that of other European peoples as well, since these peoples have 'in their totality a Germanic culture'. The difference between Greek and Germanic philosophy lies in the fact that Greek philosophy was not yet in a position to comprehend the conception of spirit in all its profundity. This only became possible through Christianity and its acceptance throughout the Germanic world. For only in this historical context was it possible for the insight to establish itself that the essence of spirit is subjectivity and hence cognition of itself. Hegel regards it as a great merit of his philosophy that it adequately explains this, and thus reconciles reason with reality in thought. In the last analysis, his message consists of a single proposition: Reason is and knows itself to be the ultimate reality. His system is brought to a conclusion in what is, in his view, a successful justification of that proposition. Even during the nineteenth century, the optimism of reason underlying Hegel's system aroused criticism, for example, from Nietzsche, Kierkegaard and the representatives of Neo-Kantianism. It seems doubtful whether, at the beginning of the twenty-first century, Hegel's indomitable faith in reason can continue to convince.

HEGELIANISM

As an intellectual tradition, the history of Hegelianism is the history of the reception and influence of the thought of G.W.F. Hegel. This tradition is notoriously complex and many-sided, because while some Hegelians have seen themselves as merely defending and developing his ideas along what they took to be orthodox lines, others have sought to 'reform' his system, or to appropriate individual aspects and overturn others, or to offer consciously revisionary readings of his work. This makes it very hard to identify any body of doctrine common to members of this tradition, and a wide range of divergent philosophical views can be found among those who (despite this) can none the less claim to be Hegelians.

There are both 'internal' and 'external' reasons for this: on one hand, Hegel's position itself brings together many different tendencies (idealism and objectivism, historicism and absolutism, rationalism and empiricism, Christianity and humanism, classicism and modernism, a liberal view of civil society with an organicist view of the state); any balance between them is hermeneutically very unstable, enabling existing readings to be challenged and old orthodoxies to be overturned. On the other hand, the critical response to Hegel's thought and the many attempts to undermine it have meant that Hegelians have continually needed to reconstruct his ideas and even to turn Hegel against himself, while each new intellectual development, such as Marxism, pragmatism, phenomenology or existential philosophy, has brought about some reassessment of his position. This feature of the Hegelian tradition has been heightened by the fact that Hegel's work has had an impact at different times over a long period and in a wide range of countries, so that divergent intellectual, social and historical pressures have influenced its distinct appropriations. At the hermeneutic level, these appropriations have contributed greatly to keeping the philosophical understanding of Hegel alive and open-ended, so that our present-day conception of his thought cannot properly be separated from them. Moreover, because questions of Hegel interpretation have so often revolved around the main philosophical, political and religious issues of the nineteenth and twentieth centuries, Hegelianism has also had a significant impact on the development of modern Western thought in its own right.

As a result of its complex evolution, Hegelianism is best understood historically, by showing how the changing representation of Hegel's ideas have come about, shaped by the different critical concerns, sociopolitical conditions and intellectual movements that dominated his reception in different countries at different times. Initially, Hegel's influence was naturally most strongly felt in Germany as a comprehensive, integrative philosophy that seemed to do justice to all realms of experience and promised to preserve the Christian heritage in a modern and progressive form within a speculative framework. However, this position was quickly challenged, both from other philosophical standpoints (such as F.W.J. Schelling's 'positive philosophy' and F.A. Trendelenburg's neo-Aristotelian empiricism), and by the celebrated generation of younger thinkers (the so-called 'Young' or 'Left' Hegelians, such as Ludwig Feuerbach, David Strauss, Bruno Bauer, Arnold Ruge and the early Karl Marx), who insisted that to discover what made Hegel a truly significant thinker (his dialectical method, his view of alienation, his 'sublation' of Christianity), this orthodoxy must be overturned. None the less, both among these radicals and in academic circles, Hegel's influence was considerably weakened in Germany by the 1860s and 1870s, while by this time developments in Hegelian thought had begun to take place elsewhere.

Hegel's work was known outside Germany from the 1820s onwards, and Hegelian schools developed in northern Europe, Italy, France, Eastern Europe, America and (somewhat later) in Britain, each with their own distinctive line of interpretation, but all fairly uncritical in their attempts to assimilate his ideas. However, in each of these countries challenges to the Hegelian position were quick to arise, partly because the influence of Hegel's German critics soon spread abroad, and partly because of the growing impact of other philosophical positions (such as Neo-Kantianism, materialism and pragmatism). Nevertheless, Hegelianism outside Germany proved more durable in the face of these attacks, as new readings and approaches emerged to counter them, and ways were found to reinterpret Hegel's work to show that it could accommodate these other positions, once the earlier accounts of Hegel's metaphysics, political philosophy and philosophy of religion (in particular) were rejected as too crude.

This pattern has continued into the twentieth century, as many of the movements that began by

defining themselves *against* Hegel (such as Neo-Kantianism, Marxism, existentialism, pragmatism, post-structuralism and even 'analytic' philosophy) have then come to find unexpected common ground, giving a new impetus and depth to Hegelianism as it began to be assimilated within and influenced by these diverse approaches. Such efforts at rapprochement began in the early part of the century with Wilhelm Dilthey's attempt to link Hegel with his own historicism, and although they were more ambivalent, this connection was reinforced in Italy by Benedetto Croce and Giovanni Gentile. The realignment continued in France in the 1930s, as Jean Wahl brought out the more existentialist themes in Hegel's thought, followed in the 1940s by Alexander Kojève's influential Marxist readings. Hegelianism has also had an impact on Western Marxism through the writings of the Hungarian Georg Lukács, and this influence has continued in the critical reinterpretations offered by members of the Frankfurt School, particularly Theodor W. Adorno, Max Horkheimer, Herbert Marcuse, Jürgen Habermas and others. More recently, most of the major schools of philosophical thought (from French post-structuralism to Anglo-American 'analytic' philosophy) have emphasized the need to take account of Hegel, and as a result Hegelian thought (both exegetical and constructive) is continually finding new directions.

HEIDEGGER, MARTIN (1889–1976)

Introduction

Martin Heidegger taught philosophy at Freiburg University (1915–23), Marburg University (1923–8), and again at Freiburg University (1928–45). Early in his career he came under the influence of Edmund Husserl, but he soon broke away to fashion his own phenomenological philosophy. His most famous work, *Sein und Zeit* (*Being and Time*) was published in 1927. Heidegger's energetic support for Hitler in 1933–4 earned him a suspension from teaching from 1945 to 1950. In retirement he published numerous works, including the first volumes of his *Gesamtausgabe* (*Collected Edition*). His thought has had strong influence on trends in philosophy ranging from existentialism through hermeneutics to deconstruction, as well as on the fields of literary theory and theology.

Heidegger often makes his case in charged and dramatic language that is difficult to convey in summary form. He argues that mortality is our defining moment, that we are thrown into limited worlds of sense shaped by our being-towards-death, and that finite meaning is all the reality we get. He claims that most of us have failed to understand that radical finitude is the source of all meaning. The result of this forgetfulness is the planetary desert called nihilism, with its promise that a virtually omnipotent and ideally omniscient humanity can remake the world in its own image. Nonetheless, he holds out the hope of recovering our finite human nature, but only at the price of accepting a nothingness darker than the nihilism that now ravishes the globe. To the barely whispered admission, 'I hardly know anymore who and where I am', Heidegger answers: 'None of us knows that, as soon as we stop fooling ourselves' (*Gelassenheit* 1959).

And yet he claims to be no pessimist. He merely wants to demonstrate (1) the phenomenological principle that 'being = meaningfulness' (the two are interchangeable) and (2) the ontological principle that all the meaningfulness we encounter is grounded in the radical finitude of human being. Heidegger's main work, *Being and Time*, was such a phenomenological ontology, an investigation of human being so as to demonstrate the finitude of all forms of meaning. Only half of the book was published in 1927, but Heidegger elaborated the rest of the project in a less systematic form during the two decades that followed.

Heidegger distinguishes between things (whatever-is) and the 'world', that is, the context within which they happen to be found. A 'world' is an arena of human concerns and interests. Any such world (that of carpentry, for example, or child-rearing, or poetry) is what constitutes the meaning of the things encountered within those worlds (hammers, for example, or nappies, or words). The 'world' of a set of entities is the 'being' of those entities, that is, that which lets them *be meaningful*. Heidegger calls this distinction between world and entities the 'ontological difference'. He argues that only human beings understand this difference, and therefore only they can make sense of things and thus have language in the full sense of the term. Rewriting Aristotle's *topos eidōn*, Heidegger calls human being 'the place of meaning', the *Da of Sein: Dasein*.

Heidegger argues that Dasein is intrinsically temporal, not in the usual chronological sense of past-present-future, but in a unique existential sense. Dasein always ek-sists (stands-out) into its own possibilities (the future). Human being is

therefore always in a state of becoming, and ultimately is becoming its own death ('being-unto-death'). When used of Dasein, the word temporality indicates not chronological succession but Dasein's finite becoming, delimited by mortality.

If Dasein's being is thoroughly finite, then all of human awareness is conditioned by this finitude, including all understanding of meaning or being. For Dasein, meaning is always known finitely and indeed is finite. The main thesis of *Being and Time* is that all worlds of meaning (all possibilities of *being meaningful*) are necessarily finite because Dasein, their source, is radically finite. Heidegger arrives at these conclusions by way of a phenomenological analysis of how Dasein opens up ('dis-closes') worlds of significance by living finitely ('anticipating its own death'). The disclosure of finite worlds of sense – how it comes about, what structure it has, and what it makes possible – is the central topic of Heidegger's thought.

But even as it dis-closes worlds of sense, Dasein's finitude remains relatively concealed even from ourselves. We tend to overlook the finitude that is the source of the disclosure of worlds and to focus instead on what get revealed *within* those worlds: meaningful entities. This overlooking is what Heidegger calls the 'forgottenness of being', a shorthand phrase for: the forgottenness of the disclosive *source* of all forms of being/meaning. Finitude is not a thing but a 'nothing', and as such it remains 'hidden'. Given its intrinsic hiddenness, this nothingness, even though it is the source of all meaning, is virtually bound to be overlooked. Heidegger argues that the forgetting of finitude characterizes not only everyday human existence ('fallenness') but also the entire history of metaphysics from Plato to Nietzsche.

Heidegger calls for Dasein to resolutely reappropriate its own radical finitude as the source of the disclosure of all meaningfulness. In so doing, Dasein becomes authentically itself as well as the guardian of what Heidegger calls 'the house of being', that is, the finite domain of sense.

1 Life and works

Martin Heidegger was born on 26 September 1889 in Messkirch, Southwest Germany, to Roman Catholic parents of very modest means. From 1899 to 1911 he intended to become a priest, but after two years of theological studies at Freiburg University a recurring heart condition ended those hopes. In 1911 he switched to mathematics and the natural sciences, but finally took his doctorate in philosophy (1913) with a dissertation entitled *Die Lehre vom Urteil im Psychologismus* (The Doctrine of Judgment in Psychologism) (1914). Hoping to get appointed to Freiburg's chair in Catholic philosophy, he wrote a qualifying dissertation in 1915 on a theme in medieval philosophy, *Die Kategorien- und Bedeutungslehre des Duns Scotus* (Duns Scotus' Doctrine of Categories and Meaning) (1916). However, the job went to someone else, and in the autumn of 1915 Heidegger began his teaching career at Freiburg as a lecturer.

At this time Heidegger was known as a Thomist, but his 1915 dissertation was strongly influenced by the founder of phenomenology, Edmund Husserl. When Husserl joined the Freiburg faculty in the spring of 1916, Heidegger came to know him personally, if not well. Their relation would blossom only after the First World War. Heidegger was drafted in 1918 and served as a weatherman on the Ardennes front in the last three months of the war. When he returned to Freiburg his philosophical career took a decisive turn. In a matter of weeks he announced his break with Catholic philosophy (9 January 1919), got himself appointed Husserl's assistant (21 January), and began lecturing on a radical new approach to philosophy (4 February).

Many influences came to bear on Heidegger's early development, including St Paul, Augustine, Meister Eckhart, Kierkegaard, Dilthey and Nietzsche. But the major influences were Husserl and Aristotle. Heidegger was Husserl's protégé in the 1920s, but he never was a faithful disciple. He preferred Husserl's early work, *Logische Untersuchungen* (Logical Investigations) (1900–1), to the exclusion of the master's later developments. Moreover, the things that Heidegger liked about *Logical Investigations* were generally consonant with the traditional scholastic philosophy he had been taught.

First, Husserl's early phenomenology considered the human 'psyche' not as a substantial thing but as an act of revealing (intentionality), one that revealed not only *what* is encountered (the entity) but also the *way in which* it is encountered (the entity's being). Second, the early Husserl held that the central issue of philosophy was not modern subjectivity but rather 'the things themselves', whatever they might happen to be, in their very appearance; and he provided a descriptive method for letting those things show themselves as they are. Third, phenomenology argued that the being of entities is known not by some after-the-fact

reflection or transcendental construction but directly and immediately by way of a categorial intuition. In short, for Heidegger, phenomenology was a descriptive method for understanding the being of entities as it is disclosed in intentional acts (see PHENOMENOLOGICAL MOVEMENT).

As Heidegger took it, all this contrasted with Husserl's later commitment to pure consciousness as the presuppositionless 'thing itself' that was to be revealed by various methodological 'reductions'. Heidegger had no use either for the Neo-Kantian turn to transcendental consciousness that found expression in Husserl's *Ideen* (Ideas) (1913) or for his further turn to a form of Cartesianism. Against Husserl's later theory of an unworldly transcendental ego presuppositionlessly conferring meaning on its objects, Heidegger proposed the historical and temporal situatedness of the existential self, 'thrown' into the world, 'fallen' in among entities in their everyday meanings, and 'projecting' ahead towards death.

In the 1920s Heidegger began interpreting the treatises of ARISTOTLE as an implicit phenomenology of everyday life without the obscuring intervention of subjectivity. He took Aristotle's main topic to be 'disclosure' (*alētheia*) on three levels: entities as intrinsically self-disclosive; human *psyche* as co-disclosive of those entities; and especially the human disclosure of entities in discursive, synthetic activity (*logos*), whether that be performed in wordless actions or in articulated sentences. Going beyond Aristotle, Heidegger interpreted this discursive disclosure as grounded in a kind of movement that he named 'temporality', and he argued that this temporality was the very essence of human being.

Using this new understanding of human being, Heidegger reinterpreted how anything at all appears to human beings. He argued that humans, as intrinsically temporal, have only a temporal understanding of whatever entities they know. But humans understand an entity by knowing it in its being, that is, in terms of how it happens to be present. Therefore, as far as human being goes, all forms of being are known temporally and indeed *are* temporal. The meaning of being is time.

Heidegger developed this thesis gradually, achieving a provisional formulation in *Sein und Zeit* (Being and Time) (1927). In public he dedicated the book to Husserl 'in respect and friendship', but in private he was calling Husserl's philosophy a 'sham' (*Scheinphilosophie*). Meanwhile, in 1923 an unsuspecting Husserl helped Heidegger move from a lecturer's job at Freiburg to a professorship at Marburg University; and when Husserl retired in 1928, he arranged for Heidegger to succeed him in the chair of philosophy at Freiburg. Once Heidegger had settled into the new job, the relationship between mentor and protégé quickly fell apart. If *Being and Time* were not enough, the three works Heidegger published in 1929 – 'Vom Wesen des Grundes' ('On the Essence of Ground'), *Kant und das Problem der Metaphysik* (Kant and the Problem of Metaphysics), and *Was ist Metaphysik?* (What is Metaphysics?) – confirmed how far apart the two philosophers had grown.

Heidegger's career entered a new phase when the Nazis came to power in Germany. On 30 January 1933 Adolf Hitler was appointed Chancellor, and within a month the German constitution and all-important civil rights were suspended. On 23 March Hitler became dictator of Germany, with absolute power to enact laws, and two weeks later, harsh anti-Semitic measures were promulgated. A conservative nationalist and staunch anti-Communist, Heidegger supported Hitler's policies with great enthusiasm for at least one year, and with quieter conviction for some ten years thereafter. He was elected rector (president) of Freiburg University on 21 April 1933 and joined the Nazi Party on May 1, with the motive, he later claimed, of preventing the politicization of the university. In his inaugural address as rector, *Die Selbstbehauptung der deutschen Universität* (The Self-Assertion of the German University) (27 May 1933), he called for a reorganization of the university along the lines of some aspects of the Nazi revolution. As rector he proved a willing spokesman for, and tool of, Nazi policy both foreign and domestic.

Heidegger resigned the rectorate on 23 April 1934 but continued to support Hitler. His remarks in the classroom indicate that he backed the German war aims, as he knew them, until at least as late as the defeat at Stalingrad in January 1943. The relation, or lack of it, between Heidegger's philosophy and his political sympathies has long been the subject of heated debate.

Heidegger published relatively little during the Nazi period. Instead, he spent those years rethinking his philosophy and setting out the parameters it would have, both in form and focus, for the rest of his life. The revision of his thought is most apparent in three texts he published much later: (1) the working notes from 1936–8 that he gathered into *Beiträge zur Philosophie. Vom Ereignis* (Contributions to Philosophy: On Ereignis), published posthumously in 1989; (2) the two volumes of his *Nietzsche*, published in 1961, which contain lecture courses and notes dating from 1936 to 1946; and (3) 'Brief über den Humanismus' ('Letter on Humanism'), written in the autumn of 1946 and published in 1947.

After the war Heidegger was suspended from teaching because of his Nazi activities in the 1930s.

In 1950, however, he was allowed to resume teaching, and thereafter he occasionally lectured at Freiburg University and elsewhere. Between 1950 and his death he published numerous works, including the first volumes of his massive *Gesamtausgabe* (Collected Edition). He died at his home in Zähringen, Freiburg, on 26 May 1976 and was buried in his home town of Messkirch. His literary remains are held at the German Literary Archives, at Marbach on the Neckar.

Heidegger, a Catholic, married Elfride Petri (1893–1992), a Lutheran, on 21 March 1917. They had two sons, both of whom served in the Wehrmacht during the Second World War and were taken prisoner on the Eastern Front. In February of 1925 Heidegger began a year-long affair with his then student, Hannah Arendt. In February of 1950 they resumed a strong but often stormy friendship that lasted until Arendt's death.

2 Temporality and authenticity

Heidegger was convinced that Western philosophy had misunderstood the nature of being in general and the nature of human being in particular. His life's work was dedicated to getting it right on both scores.

In his view, the two issues are inextricably linked. To be human is to disclose and understand the being of whatever there is. Correspondingly, the being of an entity is the meaningful presence of that entity within the field of human experience. A proper or improper understanding of human being entails a proper or improper understanding of the being of everything else. In this context 'human being' means what Heidegger designates by his technical term 'Dasein': not consciousness or subjectivity or rationality, but that distinctive kind of entity (which we ourselves always are) whose being consists in disclosing the being both of itself and of other entities. The being of this entity is called 'existence' (see §4).

Heidegger argues that the structure of human being is comprised of three co-equal moments: becoming, alreadiness and presence. (These are usually, and unfortunately, translated as: 'coming towards itself', 'is as having been' and 'making-present'.) As a unity, these three moments constitute the essence of human being, which Heidegger calls 'temporality': opening an arena of meaningful presence by anticipating one's own death. Temporality means being present by becoming what one already is.

Becoming. To be human means that one is not a static entity just 'there' among other things. Rather, being human is always a process of becoming oneself, living into possibilities, into one's future. For Heidegger, such becoming is not optional but necessary. He expresses this claim in various co-equal formulas: (1) the essence of human being is 'existence' understood as 'ek-sistence', an ineluctable 'standing out' into concern about one's own being and into the need to become oneself; (2) the essence of human being is 'factical', always already thrust into concernful openness to itself and thus into the ineluctability of self-becoming; and (3) the essence of being human is 'to be possible' – not just able, but above all needing, to become oneself.

The ultimate possibility into which one lives is the possibility to end all possibilities: one's death. Human beings are essentially finite and necessarily mortal, and so one's becoming is an anticipation of death. Thus, to know oneself as becoming is to know oneself, at least implicitly, as mortal. Heidegger calls this mortal becoming 'being-unto-death'.

Alreadiness. Human being consists in becoming; and this becoming means becoming what one already is. Here the word 'already' means 'essentially', 'necessarily' or 'inevitably'. 'Alreadiness' (*Gewesenheit*) names one's inevitable human essence and specifically one's mortality. In becoming the finitude and mortality that one already is, one gets whatever presence one has.

Presence. Mortal becoming is the way human being (a) is meaningfully present to itself and (b) renders other entities meaningfully present to itself. To put the two together: things are present to human being in so far as human being is present to itself as mortal becoming. In both cases presence is bound up with absence.

How human being is present to itself. Since mortal becoming means becoming one's own death, human being appears as disappearing; it is present to itself as becoming absent. To capture this interplay of presence and absence, we call the essence of human being 'pres-abs-ence', that is, an incomplete presence that shades off into absence. Pres-abs-ence is a name for what classical philosophy called 'movement' in the broad sense: the momentary presence that something has on the basis of its stretch towards the absent.

Pres-abs-ence is an index of finitude. Any entity that appears as disappearing, or that has its current presence by anticipating a future state, has its being not as full self-presence but as finite pres-abs-ence. The movement towards death that defines human being is what Heidegger calls 'temporality'. The quotation marks indicate that 'temporality' does not refer to chronological succession but rather means having one's being as the movement of finite mortal becoming.

How other things are present to human being. Other entities are meaningfully present to human being in so far as human being is temporal, that is, always

anticipating its own absence. Hence the meaningful presence of things is also temporal or pres-abs-ent – always partial, incomplete and entailing an absence of its own. Not only is human being temporal but the presence of things to human being is also temporal in its own right.

All of Heidegger's work argues for an intrinsic link between the temporality or pres-abs-ence that defines human being and the temporality or pres-abs-ence that characterizes the meaningful presence of things. But the meaningful presence of things is what Heidegger means by being. Therefore, Heidegger's central thesis is this: as far as human experience goes, all modes of being are temporal. The meaningful presence of things is always imperfect, incomplete, pres-abs-ential. The meaning of being is time.

Heidegger argues that this crucial state of affairs – finite human being as an awareness of the finitude of all modes of being – is overlooked and forgotten both in everyday experience and in philosophy itself. Therefore, his work discusses how one can recover this forgotten state of affairs on both of those levels.

As regards everyday life, Heidegger describes how one might recall this central but forgotten fact and make it one's own again. The act of reappropriating one's own essence – of achieving a personal and concrete grasp of oneself as finite – is called 'resolution' (in other translations, 'resoluteness' or 'resolve'). This personal conversion entails becoming clear about the intrinsic finitude of one's own being, and then choosing to accept and to be that finitude.

Awareness of one's finitude. Human being is always already the process of mortal becoming. However, one is usually so absorbed in the things one encounters ('fallenness') that one forgets the becoming that makes such encounters possible. It takes a peculiar kind of experience, more of a mood than a detached cognition, to wake one up to one's finitude. Heidegger argues that such an awakening comes about in special 'basic moods' (dread, boredom, wonder and so on) in which one experiences not things but that which is not-a-thing or 'no-thing'. Each of these basic moods reveals, in its own particular way, the absential dimension of one's pres-abs-ence.

Heidegger often uses charged metaphors to discuss this experience. For example, he describes dread as a 'call of conscience', where 'conscience' means not a moral faculty but the heretofore dormant, and now awakening, awareness of one's finite nature. What this call of conscience reveals is that one is 'guilty', not of some moral fault but of an ontological defect: the fact of being intrinsically incomplete and on the way to absence. The call of conscience is a call to understand and accept this 'guilt'.

Choosing one's finitude. One may choose either to heed or to ignore this call of conscience. To heed and accept it means to acknowledge oneself as a mortal process of pres-abs-ence and to live accordingly. In that case, one recuperates one's essence and thus attains 'authenticity' by becoming one's proper (or 'authentic') self. To ignore or refuse the call does not mean to cease being finite and mortal but rather to live according to an improper (inauthentic or 'fallen') self-understanding. Only the proper or authentic understanding of oneself as finite admits one to the concrete, experiential understanding that all forms of being, all ways that things can be meaningfully present, are themselves finite.

Summary. The essence of human being is temporality, that is, mortal becoming or pres-abs-ence. To overlook mortal becoming is to live an inauthentic temporality and to be a fallen self. But to acknowledge and choose one's mortal becoming in the act of resolution is to live an authentic temporality and selfhood. It means achieving presence (both the presence of oneself and that of other entities) by truly becoming what one already is. This recuperation of one's own finite being can lead to the understanding that what conditions *all* modes of being is finitude: the very meaning of being is time.

3 Being-in-the-world and hermeneutics

In *Being and Time* Heidegger spells out not only the reasons why, but also the ways in which, things are meaningfully present to human being.

Being-in-the-world. In contrast to theories of human being as a self-contained theoretical ego, Heidegger understands human being as always 'outside' any supposed immanence, absorbed in social intercourse, practical tasks and its own interests. Evidence for this absorption, he argues, is that human being always finds itself caught up in a mood – that is, 'tuned in' to a given set of concerns. The field of such concerns and interests Heidegger calls the 'world'; and the engagement with those needs and purposes and the things that might fulfil them he calls 'being-in-the-world' (or equally 'care').

Heidegger's term 'world' does not mean planet earth, or the vast expanse of space and time, or the sum total of things in existence. Rather, 'world' means a dynamic set of relations, ultimately ordered to human possibilities, which lends meaning or significance to the things that one deals with – as in the phrase 'the world of the artist' or 'the world of the carpenter'. A human being lives in many such worlds, and they often overlap, but what constitutes

their essence – what Heidegger calls the worldhood of all such worlds – is the significance that accrues to things by their relatedness to human interests and possibilities. Although being-in and world can be distinguished, they never occur separately. Any set of meaning-giving relations (world) comes about and remains effective only in so far as human being is engaged with the apposite possibilities (being-in). Being-in holds open and sustains the world.

In *Being and Time* Heidegger studies the world that he considers closest to human beings: the world of everyday activity. The defining moment of such a world is practical purposes ordered to human concerns – for example, the need to build a house for the sake of shelter. A group of things then gets its significance from the direct or indirect relation of those things to that goal. For example, these specific tools get their significance from their usefulness for clearing the ground, those trees get their significance from being suitable for lumber, these plants from their serviceability as thatch. A dynamic set of such relations (such as 'useful to', 'suitable as', 'needed for'), all of which refer things to a human task and ultimately to a human possibility, constitutes a 'world' and defines the current significance that certain things (for example, tools, trees and reeds) might have.

The significance of things changes according to the interplay of human interests, the relations that they generate, and the availability of material. For example, given the lack of a mallet, the significance of a stone might be its utility for pounding in a tent peg. The stone gets its current significance as a utensil from the world of the camper: the desire for shelter, the need of something to hammer with, and the availability of only a stone. (When the camper finds a mallet, the stone may well lose its former significance.)

Hermeneutical understanding. Heidegger argues that the world of practical experience is the original locus of the understanding of the being of entities. Understanding entails awareness of certain relations: for example, the awareness of this *as* that, or of this *as for* that. The 'as' articulates the significance of the thing. In using an implement, one has a practical understanding of the implement's relation to a task (X as useful for Y). This in turn evidences a practical understanding of the being of the implement: one knows the stone as *being* useful for pounding in a tent peg. In other words, prior to predicative knowledge, which is expressed in sentences of the type 'S is P', human beings already have a pre-theoretical or 'pre-ontological' understanding of the being of things (this as *being for* that).

Since the 'as' articulates how something is understood, and since the Greek verb *hermeneuein* means 'to make something understandable', Heidegger calls the 'as' that renders things intelligible in practical understanding the 'hermeneutical as'. This 'hermeneutical as' is made possible because human being is a 'thrown project', necessarily thrust into possibilities (thrownness) and thereby holding the world open (project).

Hermeneutical understanding – that is, pre-predicatively understanding the 'hermeneutical as' by being a thrown project – is the kind of cognition that most befits being-in-the-world. It is the primary way in which humans know the being of things. By contrast, the more detached and objective 'apophantic' knowledge that expresses itself in declarative sentences ('S is P') is evidence, for Heidegger, of a derivative and flattened-out understanding of being.

Summary. As long as one lives, one is engaged in mortal becoming. This becoming entails having purposes and possibilities. Living into purposes and possibilities is how one has things meaningfully present. The ability to have things meaningfully present by living into possibilities is called being-in-the-world. Being-in-the-world is structured as a thrown project: holding open the possibility of significance (project) by ineluctably living into possibilities (thrownness). This issues in a pre-predicative, hermeneutical understanding of the being of things. Thus mortal becoming *qua* being-in-the-world engenders and sustains all possible significance. In another formulation: temporality determines all the ways that things can have meaningful presence. Time is the meaning of all forms of being.

4 Dasein and disclosure

Heidegger calls human being 'Dasein', the entity whose being consists in disclosing and understanding being, whether the being of itself or that of other entities. In so far as Dasein's being is a disclosure of its *own* being, it is called 'existence' or 'ek-sistence': self-referential standing-out-unto-itself. Dasein's very being consists in being related, with understanding and concern, to itself.

But Dasein is not just related to itself. Existence occurs only as being-in-the-world; that is, the openness of human being to itself entails the openness of the world for other entities. One of Heidegger's neologisms for 'openness' is 'the there' (*das Da*), which he uses in two interrelated senses. First, human being is its own 'there': as a thrown project, existence sustains its own openness to itself. And second, in so doing, human being also makes possible the world's openness as the 'there' for other entities. Human being's self-disclosure makes possible the disclosure of other entities.

Heidegger calls human being in both these capacities 'being-the-there' – Dasein, or sometimes

Da-sein when it refers to the second capacity. In ordinary German *Dasein* means existence in the usual sense: being there in space and time as contrasted with not being at all. However, in Heidegger's usage Dasein means being disclosive of something (whether that be oneself or another entity) in its being. In a word, Dasein is disclosive. And since human being is radically finite, disclosure is radically finite.

The Greek word for disclosure is *alētheia*, a term composed of the privative prefix *a-* (un- or dis-) and the root *lēthē* (hiddenness or closure). Heidegger finds the finitude of dis-closure inscribed in the word *a-lētheia*. To disclose something is to momentarily rescue it from (*a-*) some prior unavailability (*lēthē*), and to hold it for a while in presence.

Heidegger discusses three levels of disclosure, ranging from the original to the derivative, each of which involves Dasein: (1) disclosure-as-such, (2) the disclosedness of entities in their being, and (3) disclosure in propositional statements. Heidegger's chief interest is in the first. There, disclosure/*alētheia* is the original occurrence that issues in meaningful presence (being).

Heidegger argues that levels 1 and 2 are distinct but inseparable and, taken together, make possible level 3. The word 'truth' properly applies only at the third level, where it is a property of statements that correctly represent complex states of affairs. Therefore, to the question 'What is the essence of truth?' – that is, 'What makes the truth of propositions possible at level 3?' – Heidegger answers: proximally, the disclosure of entities in their being (level 2); and ultimately, disclosure-as-such (level 1). His argument unfolds as follows.

Level 1. Disclosure-as-such is the very opening-up of the field of significance. It is the engendering and sustaining of world on the basis of Dasein's becoming-absent. In so far as it marks the birth of significance and the genesis of being, disclosure-as-such or world-disclosure is the reason why any specific entity can have meaningful presence at all.

There are three corollaries. First, the disclosure of world never happens except in Dasein's being; indeed, without Dasein, there is no openness at all. The engendering and sustaining of the dynamic relations that constitute the very possibility of significance occurs only as long as Dasein exists as mortal becoming. And conversely, wherever there is Dasein, there is world. Second, disclosure-as-such never happens apart from the disclosedness of *entities* as being this or that. In speaking of disclosure 'as such', Heidegger is naming the originating source and general structure of all possible significance that might accrue to any entity at all. The result of disclosure-as-such is the fact that referral-to-mortal-Dasein (that is, significance) is the basic state of whatever entities happen to show up. Third, disclosure-as-such is always prior to and makes possible concrete human action in any specific world. Such concrete actions run the risk of *not* being disclosive (that is, being mistaken about the meaning of something). By contrast, world-disclosure is *always* disclosive in so far as it is the opening-up of the very possibility of significance at all.

Alētheia/disclosure-as-such – how it comes about, the structure it has, and what it makes possible – is the central topic or 'thing itself' of Heidegger's thought. He sometimes calls it the 'clearing' of being. He also calls it 'being itself' or 'being-as-such' (that is, the very *engendering* of being). Frequently, and inadequately, he calls it the 'truth' of being.

Level 2. What disclosure-as-such makes possible is the pre-predicative availability of entities in their current mode of being. This pre-predicative availability constitutes level 2, the basic, everyday disclosedness of entities as meaningfully present. This disclosedness is always finite, and that entails two things.

First, what disclosure-as-such makes possible is not simply the being of an entity but rather the being of that entity as or as not something: for instance, this stone as not a missile but as a hammer. I know the stone only in terms of one or another of its possibilities: the entity becomes present not fully and immediately but only partially and discursively. Thus the entity's being is always finite, always a matter of synthesis-and-differentiation: being-as-and-as-not. Second, disclosure-as-such lets an entity be present not in its eternal essence but only in its current meaning in a given situation; moreover, it shows that this specific entity is not the only one that might have this meaning. For example, in the present situation I understand this stone not as a paperweight or a weapon but as a hammer. I also understand it as not the best instrument for the job: a mallet would do better.

Even though it is a matter of synthesis-and-differentiation, this pre-predicative hermeneutical understanding of being requires no thematic articulation, either mental or verbal, and no theoretical knowledge. It usually evidences itself in the mere doing of something. Nevertheless, in a more developed but still pre-predicative moment, such a hermeneutical awareness might evolve into a vague sense of the entity's being-this-or-that ('whatness'), being-in-this-way-or-that ('howness'), and being-available-at-all ('thatness'). Still later, these vague notions might lose the sense of *current* meaningfulness and develop, at level 3, into the explicit metaphysical concepts of the essence, modality and existence of the entity.

The second level of disclosure may be expressed in the following thesis: within any given world, to be an entity is to be always already disclosed as something or other. This corresponds to the traditional doctrine of metaphysics concerning a trans-generic (transcendental) characteristic of anything that is: regardless of its kind or species, every entity is intrinsically disclosed in its being (*omne ens est verum*).

Heidegger argues that while it is based on and is even aware of this second level of disclosure, metaphysics has no explicit understanding of disclosure-as-such or of its source in being-in-the-world. What is more, he claims that the disclosedness of entities-in-their-being (level 2) tends to overlook and obscure the very disclosure-as-such (level 1) that originally makes it possible. He further argues that there is an intrinsic hiddenness about disclosure-as-such, which makes overlooking it virtually inevitable (see §6).

Level 3. Being-in-the-world and the resultant pre-predicative disclosedness of entities as being-thus-and-so make it possible for us to enact the predicative disclosure of entities. At this third level of disclosure we are able to represent correctly to ourselves, in synthetic judgments and declarative sentences, the way things are in the world. A correct synthetic representation of a complex state of affairs (a correct judgment) is 'true', that is, disclosive of things just as they present themselves. Such a predicative, apophantic sentence ('S is P') is able to be true only because world-disclosure has already presented an entity as significant at all and thus allowed it to be taken as thus and so. This already disclosed entity is the binding norm against which the assertion must measure itself.

At level 3, however, it is also possible to *mis*represent things in thought and language, to fail to disclose them just as they present themselves in the world. At level 1 Dasein is always and only disclosive. But with predicative disclosure at level 3 (as analogously with hermeneutical disclosure at level 2) Dasein's representing of matters in propositional statements may be either disclosive or non-disclosive, either true or false.

One of Heidegger's reasons for elaborating the levels of disclosure is to demonstrate that science, metaphysics and reason in general, all of which operate at level 3, are grounded in a more original occurrence of disclosure of which they are structurally unaware. This is what he intends by his claim 'Science does not think'. He does not mean scientists are stupid or their work uninformed, nor is he disparaging reason and its accomplishments. He means that science, by its very nature, is not focused on being-in-the-world, even though being-in-the-world is ultimately responsible for the meaningful presence of the entities against which science measures its propositions.

5 *Hiddenness,* Ereignis *and the Turn*

Hiddenness. Heidegger claims that disclosure-as-such – the very opening up of significance in Dasein's being – is intrinsically hidden and needs to remain so if entities are to be properly disclosed in their being. This intrinsic concealment of disclosure-as-such is called the 'mystery'. Since Heidegger sometimes calls disclosure-as-such 'being itself', the phrase becomes 'the mystery of being'. The ensuing claim, that the mystery of being conceals itself while revealing entities, has led to much mystification, not least among Heideggerians. Being seems to become a higher but hidden Entity that performs strange acts that only the initiated can comprehend. This misconstrual of Heidegger's intentions is not helpful.

How may we understand the intrinsic concealment of disclosure-as-such? One way is to understand the paradigm of 'movement' that informs Heidegger's discussion of revealing and concealing. Taken in the broad philosophical sense, movement is defined not as mere change of place and the like, but as the very being of entities that are undergoing the process of change. This kind of being consists in anticipating something absent, with the result that what is absent-but-anticipated determines the entity's present being. Anticipation *is* the being of such entities, and anticipation is determined from the absent-but-anticipated goal. For example, the acorn's being is its becoming an oak tree; and correspondingly the future oak tree, as the goal of the acorn's trajectory, determines the acorn's present being. Likewise, Margaret *is* a graduate student in so far as she is in movement towards her Ph.D. The still-absent degree *qua* anticipated determines her being-a-student.

The absent is, by nature, hidden. But when it is anticipated or intended, the intrinsically hidden, while still remaining absent, becomes quasi-present. It functions as the 'final cause' and *raison d'être* that determines the being of the anticipating entity. That is, even while remaining intrinsically concealed, the absent-as-anticipated 'gives being' (*Es gibt Sein*) to the anticipating entity by disclosing the entity as what it presently is. This pattern of absence-dispensing-presence holds both for the disclosure of Dasein and for the disclosure of the entities Dasein encounters.

It holds pre-eminently for Dasein. Dasein's being is movement, for Dasein exists by anticipating its own absence. Dasein's death remains intrinsically hidden, but when anticipated, the intrinsically hidden becomes quasi-present by determining Dasein's

being as mortal becoming. The absent, when anticipated, dispenses Dasein's finite presence.

The same holds for other entities. The anticipated absence determines Dasein's finite being. But Dasein's being is world-disclosive: it holds open the region of meaningful presence in which other entities are disclosed as being-this-or-that. Hence, the intrinsically hidden, when anticipated, determines the presence not only of Dasein but also of the entities Dasein encounters.

Therefore, the very structure of disclosure – that is, the fact that the absent-but-anticipated determines or 'gives' finite presence – entails that its ultimate source remain intrinsically hidden even while disclosing the being of entities. This intrinsic hiddenness at the core of disclosure is what Heidegger calls the 'mystery'. Heidegger argued that the 'mystery' is the ultimate issue in philosophy, and he believed HERACLITUS had said as much in his fragment no. 123: 'Disclosure-as-such loves to hide'.

Ereignis. The paradigm of movement also explains why Heidegger calls disclosure-as-such '*Ereignis*'. In ordinary German *Ereignis* means 'event', but Heidegger uses it as a word for movement. Playing on the adjective *eigen* ('one's own'), he creates the word *Ereignung*: movement as the process of being drawn into what is one's own. For example, we might imagine that the oak tree as final cause 'pulls' the acorn into what it properly is, by drawing the acorn towards what it is meant to be. This being-pulled is the acorn's movement, its very being. Likewise, Dasein is 'claimed' by death as its final cause and 'pulled forth' by it into mortal becoming. This being-drawn into one's own absence, in such a way that world is engendered and sustained, is what Heidegger calls 'appropriation'. It is what he means by *Ereignis*.

The word '*Ereignis*', along with the image of Dasein being appropriated by the absent, emerges in Heidegger's thought only in the 1930s. However, this later language echoes what Heidegger had earlier called Dasein's thrownness, namely, the fact that Dasein is thrust into possibilities, anticipates its self-absence, and so is 'already' involved in world-disclosure. Both the earlier language of thrown anticipation *of* absence, and the later language of appropriation *by* absence, have the same phenomenon in view: Dasein's alreadiness, its constitutive mortality that makes for world-disclosure.

The paradigm of movement also helps to clarify Heidegger's claim about the concealing-and-revealing, or withdrawing-and-arriving, of being itself (that is, of disclosure-as-such). In a quite typical formulation Heidegger writes: 'Being itself withdraws itself, but as this withdrawal, being is the "pull" that claims the essence of human being as the place of being's own arrival' (Nietzsche 1961). This sentence, which describes the structure of *Ereignis*, may be interpreted as follows:

The 'withdrawal' of disclosure-as-such

(that is, the intrinsic hiddenness of world-disclosive absence)

maintains a relation to Dasein

(which we may call either 'appropriation' or 'thrown anticipation')

that claims Dasein

(by appropriating it into mortal becoming)

so that, *in* Dasein's being,

(in so far as Dasein's being is the openness that is world)

being itself might arrive

(in the form of the relations of significance whereby entities have being-as this-or-that).

The Turn. One can notice a certain shift within Heidegger's work beginning around 1930, both in his style and in the topics he addresses. As regards style, some have claimed that his language becomes more abstruse and poetic, and his thinking less philosophical than mystical. As regards substance, he seems to introduce new topics like 'appropriation' and the 'history of being'.

The problem is to discern whether these and other shifts count as what Heidegger calls the Turn (*die Kehre*). Some argue that beginning in the 1930s Heidegger radically changed his approach and perhaps even his central topic. The early Heidegger, so the argument goes, had understood being itself (that is, disclosure-as-such) from the standpoint of Dasein, whereas the later Heidegger understands Dasein from the standpoint of being itself. But to the contrary it is clear that even the early Heidegger understood Dasein only from the standpoint of being itself.

Heidegger clarifies matters by distinguishing between (1) the Turn and (2) the 'change in thinking' that the Turn demands, both of which are to be kept distinct from (3) the various shifts in form and focus that his philosophy underwent in the 1930s. The point is that, properly speaking, the Turn is not a shift in Heidegger's thinking nor a change in his central topic. The Turn is only a further specification of *Ereignis*. There are three issues here.

First, the 'Turn' is a name for how *Ereignis* operates. *Ereignis* is the appropriation of Dasein for the sake of world-disclosure. For Heidegger, this fact stands over against all theories of the self as an autonomous subject that presuppositionlessly (that

is, without a prior world-disclosure) posits its objects in meaning. In opposition to that, *Ereignis*-means that Dasein must already be appropriated into world-disclosive absence before anything can be significant at all.

Ereignis also means that Dasein's appropriation by, or thrownness into, world-disclosive absence is the primary and defining moment in Dasein's projection of that disclosure. This reciprocity (*Gegenschwung*) between appropriation/thrownness on the one hand and projection on the other – with the priority going to appropriation/thrownness – constitutes the very structure of *Ereignis* and is what Heidegger calls the Turn. The upshot of this reciprocity is that Dasein must be already pulled into world-disclosive absence (thrown or appropriated into it) if it is to project (that is, hold open) disclosure at all. In a word, the Turn *is Ereignis*.

Second, the 'change in thinking' refers to the personal conversion that the Turn demands. To become aware of the Turn and to accept it as determining one's own being is what Heidegger had earlier called 'resolution' and what he now describes as 'a transformation in human being'. This transformation into an authentic self consists in letting one's own being be defined by the Turn.

Third, the shifts in Heidegger's work in the 1930s – and especially the development and deepening of his insights into thrownness and appropriation – are just that: shifts and developments within a single, continuing project. Important as they are, they are neither the Turn itself nor the change in personal self-understanding that the Turn requires.

6 Forgetfulness, history and metaphysics

Heidegger sees a strong connection between the forgetting of disclosure-as-such, the history of the dispensations of being, and metaphysics.

Forgetting disclosure-as-such. Because disclosure-as-such is intrinsically hidden (this is what is meant by the mystery), it is usually overlooked. When the mystery is overlooked, human being is 'fallen', that is, aware of entities as being-thus-and-so, but oblivious of what it is that 'gives' being to entities. Fallenness is forgetfulness of the mystery. Another term for fallenness is 'errancy', which conveys the image of Dasein 'wandering' among entities-in-their-being without knowing what makes their presence possible. Since disclosure-as-such is sometimes called 'being itself', fallenness is also called 'the forgetfulness of being'.

However, disclosure-as-such need not be forgotten. It is possible, in resolution, to assume one's mortality and become concretely aware of disclosure-as-such in its basic state of hiddenness. Such awareness does not undo the intrinsic hiddenness of disclosure-as-such or draw it into full presence. Rather, one accepts the concealment of being itself (this is called 'letting being be') by resolutely accepting one's appropriation by absence.

The history of the dispensations of being. Heidegger's discussions of the 'history of being' sometimes verge on the anthropomorphic, and he often uses etymologies that are difficult to carry over into English. Nevertheless, his purpose in all this is clear: to spell out the world-historical dimensions of fallenness.

As we have seen, disclosure-as-such 'gives' the being of entities while the 'giving' itself remains hidden; and this happens only in so far as Dasein is appropriated by absence. When one forgets the absence that appropriates Dasein, and thus forgets the hidden giving that brings forth the being of entities, fallenness and errancy ensue. Fallen Dasein then focuses on the given (entities-in-their-being) and overlooks the hidden giving (disclosure-as-such). None the less, the hidden giving still goes on giving, but now in a doubly hidden way: it is both intrinsically hidden *and* forgotten. When the hiddenness is forgotten, a disclosure is called a 'dispensation' (*Geschick*) of being. The word connotes a portioning-out that holds something back. A certain form of the being of entities is dispensed while the disclosing itself remains both hidden and forgotten.

In German, 'dispensation' (*Geschick*) and 'history' (*Geschichte*) have their common root in the verb *schicken*, 'to send'. Playing on those etymologies, Heidegger elaborates a 'history' of being, based on the 'sendings' or 'dispensations' of being. (The usual translations of *Geschick* as 'fate' or 'destiny' are not helpful here.) In Heidegger's view each dispensation of being defines a distinct epoch in the history of thought from ancient Greece down to today. He calls the aggregate of such dispensations and epochs the 'history of being'. Because the whole of these dispensations and epochs is correlative to fallenness, Heidegger seeks to overcome the history of being and return to an awareness of the hidden giving.

Heidegger believes the parameters of each epoch in the history of being can be glimpsed in the name that a major philosopher of the period gave to the being of entities in that age. A non-exhaustive list of such epoch-defining notions of being includes: *idea* in Plato, *energeia* in Aristotle, act in Aquinas, representedness in Descartes, objectivity in Kant, Absolute Spirit in Hegel, and will to power in Nietzsche. What characterizes each such epoch is (1) an understanding of being as some form of the presence of entities and (2) an oblivion of the absence that bestows such presence. None the less, even when forgotten the absence is never abolished,

and thus traces of it remain in the various dispensations. Therefore, in studying the texts of classical philosophy Heidegger searches for and retrieves the unexpressed absence (the 'unsaid') that hides behind what the text actually expresses (the 'said').

Metaphysics. The various ways that presence or being has been dispensed, while absence has been overlooked, are called in their entirety 'metaphysics'. Heidegger argues that metaphysics as a philosophical position which began with Plato and entered its final phase with Nietzsche.

The Greek philosophers who preceded Socrates and Plato were, in Heidegger's view, *pre*-metaphysical in so far as they had at least a penumbral awareness of disclosure-as-such and at least named it (Heraclitus, for example, called it *logos*, *alētheia*, and *physis*). However, none of these thinkers thematically addressed disclosure-as-such or understood the correlative notions of ek-sistence and Dasein. Heidegger calls the penumbral awareness of disclosure-as-such among archaic Greek thinkers the 'first beginning'. And he hoped that a 'new beginning' would follow the end of metaphysics. If the first beginning was not yet metaphysical, the new beginning will be no longer metaphysical. Heidegger considered his own work a preparation for that new beginning.

But metaphysics persists. The history of the dispensations of being has reached its fullness in the present epoch of technology. As Heidegger uses the word, 'technology' refers not to hardware or software or the methods and materials of applied science. Rather, it names a dispensation in the history of metaphysics, in fact the final one. It names the way in which entities-in-their-being are disclosed today.

Heidegger maintains that in the epoch of technology entities are taken as a stockpile of matter that is in principle completely knowable by human reason and wholly available for human use. With this notion metaphysics arrives at its most extreme oblivion of disclosure-as-such. In our time, Heidegger says, the presence of entities has become everything, while the absence that brings about that presence has become nothing. He calls this nil-status of absence 'nihilism'.

Overcoming metaphysics. None the less, Heidegger sees a glimmer of light in the dark epoch of nihilism. In this final dispensation of metaphysics, the hidden giving does not cease to function, even when it is completely forgotten. It continues dispensing presence – paradoxically even the nihilistic presence which obscures the absence that gives it. Because the hidden giving goes on giving even when it is forgotten, we can still experience it today (in a mood not unlike dread) and retrieve it. This recovery of world-disclosive absence requires resolution or, as Heidegger now calls it, 'the entrance into *Ereignis*'. To enter *Ereignis* today is to experience a different kind of *nihil* ('nothing') from the one that defines nihilism. The absence that bestows presence is itself a kind of 'nothing' (not-a-thing). This absence is no entity, nor can it be reduced to the being of any specific entity or be present the way an entity is. That is why it is so easily overlooked. Its 'nothingness' is its intrinsic hiddenness.

To enter *Ereignis* is to become aware of and to accept the disclosive *nihil* that rescues one from nihilism. Thereupon, says Heidegger, metaphysics as the history of the dispensations of being ceases and a new beginning takes place – at least for those individuals who achieve authenticity by way of resolution. But metaphysics will continue for those who remain inauthentic, because dispensation is correlative to fallenness.

Summary. The forgetting of disclosure-as-such is metaphysics. Metaphysics knows entities-in-their-being but ignores the very giving of that being. The aggregate of the epochs of metaphysics is the history of the dispensations of being. The history of these dispensations culminates in the epoch of technology and nihilism. But world-disclosive absence can still be retrieved; and when it is retrieved, it ushers in (at least for authentic individuals) a new beginning of ek-sistence and Dasein.

7 The work of art

One of Heidegger's most challenging essays is 'The Origin of the Work of Art', originally drafted in 1935 and published in an expanded version only in 1950. There he distinguishes between the work of art as a specific entity (for example, a poem or a painting) and art itself, the latter being understood not as a collective name for, but rather as the essence and origin of, all works of art. Heidegger asks what art itself is, and he answers that art is a unique kind of disclosure.

Dasein is disclosive of the being of an entity in many ways, some of them ordinary and some of them extraordinary. An outcome common to both kinds of disclosure is that the disclosed entity is seen as what it is: it appears in its form. Examples of ordinary, everyday ways of disclosing the being of entities include showing oneself to be adept at the flute, or moulding clay into a vase, or concluding that the accused is innocent. Each of these ordinary cases of praxis, production and theory does indeed disclose some entity as being this or that, but the focus is on showing what the *entity* is rather than on showing how the entity's *being* is disclosed. On the other hand, extraordinary acts of disclosure bring to

attention not only the disclosed entity but above all the event of disclosure of that entity's being. Extraordinary acts of disclosure let us see the very fact that, and the way in which, an entity has become meaningfully present in its being. In these cases not only does an entity appear in its form (as happens in any instance of disclosure), but more importantly the very disclosure of the being of the entity 'is established' (*sich einrichten*) in the entity and is seen there as such.

Heidegger lists five examples of extraordinary disclosure: the constitution of a nation-state; the nearness of god; the giving of one's life for another; the thinker's questioning as revealing that being can be questioned; and the 'installation' (*Sich-ins-Werk-Setzen*) of disclosure in a work of art. Each of these cases discloses, in its own particular way, not just an entity but the very disclosure of that entity's being. Heidegger seeks to understand the particular way in which art itself discloses disclosure by 'installing' disclosure in the work of art.

In his essay Heidegger refers mainly to two works of art: van Gogh's canvas 'Old Shoes', painted in Paris in 1886–7 and now hung in the Stedelijk Museum, Amsterdam; and the 5th century BC Doric Temple of Hera II – the so-called Temple of Poseidon – at Paestum (Lucania), Italy. Let us consider the temple at Paestum as we attempt to answer two questions: what gets disclosed in a work of art and how does it get disclosed?

(1) *What gets disclosed in a work of art?* Heidegger gives three answers. First, a work of art lets us see disclosure in the form of 'world' and 'earth'. A work of art discloses not just an entity or an ensemble of entities but the whole realm of significance whereby an ensemble of entities gets its finite meaning. The temple at Paestum not only houses (and thus discloses) the goddess Hera, but more importantly lets us see the social and historical world – rooted as it was in the natural setting of Lucania – that Hera's presence guaranteed for the Greek colonists. A work of art, Heidegger argues, reveals the very event of disclosure, which event he calls the happening of world and earth, where 'earth' refers not only to nature and natural entities but more broadly to all entities within a specific world.

Second, a work of art lets us see the radical tension that discloses a specific world of significance. Heidegger understands being-in-the-world as a 'struggle' (*Streit* or *polemos*) between a given world and its earth, between the self-expanding urge of a set of human possibilities and the rootedness of such possibilities in a specific natural environment. Here, 'struggle' is another name for the event of disclosure whereby a particular world is opened up and maintained. What a specific work of art discloses is one particular struggle that discloses one particular world – for instance, the world of the Greek colonists at Paestum.

Third, a work of art shows us disclosure-as-such. The movement of opening up a particular world is only one instance of the general movement of *alētheia*: the 'wresting' of being-at-all from the absolute absence into which Dasein is appropriated. Thus a work of art not only shows us a particular world-disclosive struggle (the way the temple of Hera shows us the earth–world tension at Paestum) but also lets us see the 'original struggle' (*Urstreit*) of disclosure-as-such, whereby significance is wrested from the double closure of intrinsic hiddenness and fallenness.

In short, what a work of art reveals is disclosure in three forms: as world and earth; as the struggle that opens up a specific world and lets its entities be meaningful; and as the original struggle that structures all such particular disclosures.

(2) *How does a work of art disclose disclosure?* The specific way that art discloses disclosure is by 'installing' it in a given work of art. Here, 'to install' means to bring to stability; and 'to install disclosure' means to incorporate it into the physical form of a work of art. There are three corollaries:

What the installing is not. Heidegger does not claim that the work of art 'sets up' the world and 'sets forth' the earth for the first time. That is, installing the disclosure of earth and world in the work of art is not the only or even the first way that earth and world get disclosed. The sanctuary of Hera was not the first to open up the world of Paestum and disclose the fields and flocks for what they are. Tradesmen and farmers had been doing that – that is, the disclosive struggle of world and earth had been bestowing form and meaning – for at least a century before the temple was built.

What the installing is and does. Art discloses, in a new and distinctive way, a disclosure of earth and world that is already operative. Heidegger argues that the temple as disclosive (a) captures and sustains the openness of that world and its rootedness in nature, and (b) shows how, within that world, nature comes forth into the forms of entities while remaining rooted in itself. Heidegger calls these two functions, which happen only in art, the 'setting up' of world and the 'setting forth' of earth.

The work of art lets us see – directly, experientially and in all its glory – the already operative interplay of human history's rootedness in nature and nature's emergence into human history. In Heidegger's words, art 'stabilizes' (*zum Stehen bringen*) the disclosive struggle of world and earth by 'installing' it in a particular work of art, such that in and through that medium, disclosure 'shines forth' brilliantly in beauty.

The two ways art discloses disclosure, and their unity. Art itself is a specific and distinctive way in which

Dasein is disclosive: it discloses disclosure by installing disclosure in the physical form of a work of art. This installation has two moments: the creation and the preservation of the work of art.

Creation is an artist's Dasein-activity of incorporating disclosure – the world-openness that is already operative – into a material medium (stone, colour, language and so on). This incorporation of disclosure is carried out in such a way that the material medium is not subordinated to anything other than disclosure (for example, it is not subordinated to 'usefulness'). Rather, the medium becomes, for whoever experiences it, the immediate disclosure of disclosure.

Preservation is the corresponding Dasein-activity of maintaining the power of disclosure in the work of art by resolutely letting disclosure continue to be seen there. Creation and preservation are the two ways that Dasein 'projects' (holds open and sustains) the disclosure that is installed in the work of art. The unity of creation and preservation is art itself, which Heidegger calls *Dichtung* – not 'poetry' but *poiesis*, the creating-and-preserving installation of disclosure in a disclosive medium.

Disclosure is the central topic of all Heidegger's philosophy, and this fact shines brilliantly through his reflection on the origin of the work of art. Art, both as creation and as preservation, is a specific and distinctive Dasein-activity: the disclosure of disclosure in a medium that is disclosive. In the work of art, as in Heidegger's own work, it's *alētheia* all the way down.

HELL

The ancient idea that the dead go to a dark subterranean place gradually evolved into the notion of divinely instituted separate postmortem destinies for the wicked and the righteous. If the former lies behind the Psalms, the latter version appears in apocalyptic works, both canonical and deutero- or non-canonical, and is presupposed by numerous passages in the New Testament. Through the patristic and medieval periods the doctrine gradually achieved ecclesiastical definition, stipulating eternal torment (both physical and spiritual) in a distinctive place for those who die in a state of mortal sin. Most reformers recognized biblical authority for this doctrine. Philosophically, the notion of postmortem survival raises many questions in the philosophy of mind about personal identity. Recent discussion, however, has concentrated on the specialized version of the problem of evil to which the doctrine gives rise.

HELMONT, FRANCISCUS MERCURIUS VAN (1614–98)

Although he lived in the seventeenth century, van Helmont belongs more to late Renaissance than to modern intellectual culture. He was a larger-than-life figure who, in his prime, had an international reputation as an alchemist and a physician. His metaphysical interests came increasingly to the fore, however, and he became particularly associated with Kabbalistic doctrines. A friend of Locke and Henry More, he was also closely connected with Anne Conway and Leibniz, with whom he shared many intellectual affinities. It is these connections that make his philosophy – in particular, his theodicy and his monadology – of enduring interest.

STUART BROWN

HERACLITUS (*c.*540–*c.*480 BC)

No Greek philosopher born before Socrates was more creative and influential than Heraclitus of Ephesus. Around the beginning of the fifth century

BC, in a prose that made him proverbial for obscurity, he criticized conventional opinions about the way things are and attacked the authority of poets and others reputed to be wise. His surviving work consists of more than 100 epigrammatic sentences, complete in themselves and often comparable to the proverbs characteristic of 'wisdom' literature. Notwithstanding their sporadic presentation and transmission, Heraclitus' sentences comprise a philosophy that is clearly focused upon a determinate set of interlocking ideas.

As interpreted by the later Greek philosophical tradition, Heraclitus stands primarily for the radical thesis that 'Everything is in flux', like the constant flow of a river. Although it is likely that he took this thesis to be true, universal flux is too simple a phrase to identify his philosophy. His focus shifts continually between two perspectives – the objective and everlasting processes of nature on the one hand and ordinary human beliefs and values on the other. He challenges people to come to terms, theoretically and practically, with the fact that they are living in a world 'that no god or human has made', a world he describes as 'an ever-living fire kindling in measures and going out in measures' (fr. 30). His great truth is that 'All things are one', but this unity, far from excluding difference, opposition and change, actually depends on them, since the universe is in a continuous state of dynamic equilibrium. Day and night, up and down, living and dying, heating and cooling – such pairings of apparent opposites all conform to the everlastingly rational formula (*logos*) that unity consists of opposites; remove day, and night goes too, just as a river will lose its identity if it ceases to flow.

Heraclitus requires his audience to try to think away their purely personal concerns and view the world from this more detached perspective. By the use of telling examples he highlights the relativity of value judgments. The implication is that unless people reflect on their experience and examine themselves, they are condemned to live a dream-like existence and to remain out of touch with the formula that governs and explains the nature of things. This formula is connected (symbolically and literally) with 'ever-living fire', whose incessant 'transformations' are not only the basic operation of the universe but also essential to the cycle of life and death. Fire constitutes and symbolizes both the processes of nature in general and also the light of intelligence. As the source of life and thought, a 'fiery' soul equips people to look into themselves, to discover the formula of nature and to live accordingly.

The influence of Heraclitus' ideas on other philosophers was extensive. His reputed 'flux' doctrine, as disseminated by his follower Cratylus, helped to shape Plato's cosmology and its changeless metaphysical foundations. The Stoics looked back to Heraclitus as the inspiration for their own conception of divine fire, identifying this with the *logos* that he specifies as the world's explanatory principle. Later still, the neo-Pyhrronist Aenesidemus invoked Heraclitus as a partial precursor of scepticism.

A.A. LONG

HERDER, JOHANN GOTTFRIED (1744–1803)

Herder was a central figure in the German intellectual renaissance of the late eighteenth century. His achievement spanned virtually every domain of philosophy, and his influence, especially upon Romanticism and German idealism, was immense. In social and political philosophy he played a prominent role in the development of historicism and nationalism. In metaphysics he developed the doctrine of vitalist pantheism, which later became important for Goethe, Schelling and Hegel. In the philosophy of mind he formulated an organic theory of the mind–body relationship, which was crucial for Schelling and Hegel. And in aesthetics he was among the first to defend the value of ethnic poetry and the need for the internal and historical understanding of a text.

Herder's main aim was to extend the powers of naturalistic explanation to the realm of culture, so that characteristic human activities, such as art, religion, law and language could be included within the scientific worldview. But he also wanted to avoid reductivistic forms of explanation that viewed such activities as nothing more than matter-in-motion or stimulus-response mechanisms. He insisted that explanation in the cultural sphere had to be holistic and internal as well as mechanical and external. An action had to be understood in its historical context and according to the intention of the agent and not simply as another instance of a causal regularity between events. Herder's programme, then, was to develop naturalistic yet non-reductivistic explanations for the realm of culture. He attempted to realize this programme in many spheres, especially language, history, religion and the mind.

HERMENEUTICS

Hermeneutics, the 'art of interpretation', was originally the theory and method of interpreting

the Bible and other difficult texts. Wilhelm Dilthey extended it to the interpretation of all human acts and products, including history and the interpretation of a human life. Heidegger, in *Being and Time* (1927), gave an 'interpretation' of the human being, the being that itself understands and interprets. Under his influence, hermeneutics became a central theme of Continental philosophy. Hermeneutics generates several controversies. In interpreting something do we unearth the author's thoughts and intentions, imagining ourselves in his position? Or do we relate it to a wider whole that gives it meaning? The latter view gives rise to the hermeneutic circle: we cannot understand a whole (for example, a text) unless we understand its parts, or the parts unless we understand the whole. Heidegger discovered another circle: as we inevitably bring presuppositions to what we interpret, does this mean that any interpretation is arbitrary, or at least endlessly revisable?

HERMETISM

A primarily religious amalgam of Greek philosophy with Egyptian and other Near Eastern elements, Hermetism takes its name from Hermes Trismegistus, 'thrice greatest Hermes', alias the Egyptian god Thoth. Numerous texts on philosophical theology and various occult sciences, ascribed to or associated with this primeval figure, were produced in Greek by Egyptians between roughly AD 100 and 300, and are a major document of late pagan piety. Reintroduced into Western Europe during the Renaissance, they provided considerable inspiration to philosophers, scientists and magicians of the fifteenth and sixteenth centuries.

JOHN PROCOPÉ

HERZEN, ALEKSANDR IVANOVICH (1812–70)

Lauded by Nietzsche as 'a man of every distinctive talent' and admired by Lenin as the founder of the Russian revolutionary movement, Herzen eludes all neat categorizations. As a moral preacher he stands alongside Tolstoi and Dostoevskii (who praised him as a poet). As a philosopher, he was the principal interpreter and popularizer of Hegel's thought in Russia in the first half of the 1840s, while the rebellion against metaphysical systems in his mature work has led him to be seen as a precursor of existentialism. Through the Russian press that he founded while an émigré he helped to shape the beginnings of a public opinion in his country and played a major role in debates on Russia's political future on the eve of the emancipation of the serfs, while laying the foundations of the Russian populist movement through his writings on Russian socialism. He is best known in the West for his memoirs, *Byloe i dumy* (*My Past and Thoughts*) (1861, 1866), which rank among the great works of Russian literature, and for *S togo berega* (*From the Other Shore*) (1850), the most brilliant and original of the works in which he expresses his rejection of all teleological conceptions of history.

AILEEN KELLY

HILBERT'S PROGRAMME AND FORMALISM

In the first, geometric stage of Hilbert's formalism, his view was that a system of axioms does not express truths particular to a given subject matter but rather expresses a network of logical relations that can (and, ideally, will) be common to other subject matters.

The formalism of Hilbert's arithmetical period extended this view by emptying even the logical terms of contentual meaning. They were treated purely as ideal elements whose purpose was to secure a simple and perspicuous logic for arithmetical reasoning – specifically, a logic preserving the classical patterns of logical inference. Hilbert believed, however, that the use of ideal elements should not lead to inconsistencies. He thus undertook to prove the consistency of ideal arithmetic with its contentual or finitary counterpart and to do so by purely finitary means.

In this, 'Hilbert's programme', Hilbert and his followers were unsuccessful. Work published by Kurt Gödel in 1931 suggested that such failure was perhaps inevitable. In his second incompleteness theorem, Gödel showed that, for any consistent formal axiomatic system T strong enough to formalize what was traditionally regarded as finitary reasoning, it is possible to define a sentence that expresses the consistency of T, and is not provable in T. From this it has generally been concluded that the consistency of even the ideal arithmetic of the natural numbers is not finitarily provable and that Hilbert's programme must therefore fail.

Despite problematic elements in this reasoning, post-Gödelian work on Hilbert's programme has generally accepted it and attempted to minimize its effects by proposing various modifications of Hilbert's programme. These have generally taken one of three forms: attempts to extend Hilbert's finitism to stronger constructivist bases capable of proving more than is provable by strictly finitary

means; attempts to show that for a significant family of ideal systems there are ways of 'reducing' their consistency problems to those of theories possessing more elementary (if not altogether finitary) justifications; and attempts by the so-called 'reverse mathematics' school to show that the traditionally identified ideal theories do not need to be as strong as they are in order to serve their mathematical purposes. They can therefore be reduced to weaker theories whose consistency problems are more amenable to constructivist (indeed, finitist) treatment.

MICHAEL DETLEFSEN

HILDEGARD OF BINGEN (1098–1179)

Hildegard of Bingen saw herself as a prophet sent by God to awaken an age in which great troubles were besieging the Church and people no longer understood Scripture. She tried to alleviate the first problem by writing letters to secular and religious leaders and preaching against those she saw as the culprits, and to this end she undertook preaching tours throughout Germany, preaching in cathedrals, monasteries and synods. Her writings, primarily interpretations of her own visions, address the second problem by trying to cast a new light on Christian revelation through illustrating it with original vivid imagery and personifications of abstract concepts. Though her works are not, for the most part, clearly philosophical, Hildegard does show philosophical insight.

CLAUDIA EISEN MURPHY

HINDU PHILOSOPHY

Hindu philosophy is the longest surviving philosophical tradition in India. We can recognize several historical stages. The earliest, from around 700 BC, was the proto-philosophical period, when karma and liberation theories arose, and the proto-scientific ontological lists in the Upaniṣads were compiled. Next came the classical period, spanning the first millennium AD, in which there was constant philosophical exchange between different Hindu, Buddhist and Jaina schools. During this period, some schools, such as Sāṅkhya, Yoga and Vaiśeṣika, fell into oblivion and others, such as Kashmir Saivism, emerged. Finally, after the classical period only two or three schools remained active. The political and economic disturbances caused by repeated Muslim invasions hampered intellectual growth. The schools that survived were the Logic school (Nyāya), especially New Logic (Navya-Nyāya), the grammarians and, above all, the Vedānta schools.

The central concerns of the Hindu philosophers were metaphysics, epistemological issues, philosophy of language, and moral philosophy. The different schools can be distinguished by their different approaches to reality, but all considered the Vedas (the sacred scriptures) authoritative, and all believed that there is a permanent individual self (*ātman*). They shared with their opponents (Buddhists and Jainas) a belief in the need for liberation. They used similar epistemic tools and methods of argument.

In contrast to their opponents, who were atheists, Hindu philosophers could be either theists or atheists. Actually we can observe an increased tendency towards theistic ideas near the end of the classical period, with the result that the strictly atheistic teachings, which were more philosophically rigorous and sound, fell into disuse. Hindu metaphysics saw *ātman* as part of a larger reality (Brahman).

Because these views of the world differed, they had to be proved and properly established. Accordingly, logical and epistemological tools were developed and fashioned according to the needs and beliefs of individual philosophers. Most agreed on two or three sources of knowledge: perception and inference, with verbal testimony as a possible third. In this quest for philosophical rigour, there was a need for precision of language, and there were important philosophical developments among the grammarians and the philosophers who explained the Vedas (the Mīmāṃsakas). A culmination of these linguistic efforts can be seen in the philosopher of language Bhartṛhari. One of his greatest accomplishments was the full articulation of the theory that a sentence as a whole is understood in a sudden act of comprehension.

It is customary to name six Hindu schools, of the more than a dozen that existed, thus lumping several into a single school. This is particularly the case with Vedānta. The six are listed in three pairs: Sāṅkhya–Yoga; Vedānta–Mīmāṃsā; Nyāya–Vaiśeṣika. This does not take account of the grammarians or Kashmir Saivism.

In their quest for freedom from rebirth, all the Hindu schools operated within the same framework. Their ultimate goal was liberation. How much they were truly engaged in the quest for liberation apart from their philosophical preoccupations is not always clear, yet they never doubted its real possibility.

EDELTRAUD HARZER CLEAR

HISTORICISM

Historicism, defined as 'the affirmation that life and reality are history alone' by Benedetto Croce, is understood to mean various traditions of historiographical thinking which developed in the nineteenth century, predominantly in Germany. Historicism is an insistence on the historicity of all knowledge and cognition, and on the radical segregation of human from natural history. It is intended as a critique of the normative, allegedly anti-historical, epistemologies of Enlightenment thought, expressly that of Kant. The most significant theorists and historians commonly associated with historicism are Leopold von Ranke, Wilhelm Dilthey, J.G. Droysen, Friedrich Meinecke, Croce and R.G. Collingwood.

The main antecedents for the development of historicism are to be found in two key bodies of work. J.G. Herder's *Outlines of a Philosophy of the History of Man* (1784) argues against the construction of history as linear progress, stating rather that human history is composed of fundamentally incomparable national cultures or totalities. G.W.F. Hegel's *The Philosophy of History* (1826) insists on the historical situatedness of each individual consciousness as a particular moment within the total progression of all history towards a final goal. The shifting fusion of these ideas provides the foundation for both the strengths and the problems of historicism. Historicism follows both Herder, in attempting to do justice to objective history in its discontinuity and uniqueness, and Hegel, in attempting to determine general patterns of historical change. Indeed, historicism can perhaps be best termed a Hegelian philosophy of history without an all-encompassing notion of progress.

Rather than constituting a unified intellectual movement, historicism is best known for its elusiveness. Its multifarious quality can be inferred from the variety of critical positions taken up against it. Influential critiques of historicism have been written by Friedrich Nietzsche, Friedrich Rickert, Ernst Troeltsch, Walter Benjamin, Karl Löwith and Karl Popper. Critical engagement with historicism has focused on its alleged relativism, its alleged particularism, its alleged claims to totality, its alleged subjectivism and its alleged objectivism. More positive debates with historicism have significantly influenced the thought of Martin Heidegger, Edmund Husserl and Hans-Georg Gadamer.

HISTORY, PHILOSOPHY OF

Philosophy of history is the application of philosophical conceptions and analysis to history in both senses, the study of the past and the past itself. Like most branches of philosophy its intellectual origins are cloudy, but they lie in a refinement of 'sacred' histories, especially those of Judaism and Christianity. The first major philosopher to outline a scheme of world history was Immanuel Kant in *The Idea of a Universal History from a Cosmopolitan Point of View* (1784), and German idealism also produced Hegel's *Lectures on the Philosophy of World History* (1837), a much longer and more ambitious attempt to make philosophical sense of the history of the world as a whole. According to Hegel, history is rational, the working out, in fact, of philosophical understanding itself.

The accelerating success of natural science in the nineteenth century gave rise to a powerful combination of empiricism and logical positivism which produced a philosophical climate highly unfavourable to Hegelian philosophy of history. The belief became widespread among philosophers that Hegel, and Marx after him, had developed a priori theories that ignored historical contingency in favour of historical necessity, and which were empirically unfalsifiable. Karl Popper's philosophy of science was especially influential in converting philosophy of history to a new concern with the methods of historical study rather than with the shape of the past. Two rival conceptions of historical method existed. One tried to model explanation in history on what they took to be the form of explanation in science, and argued for the existence of 'covering laws' by which historians connect the events they seek to explain. The other argued for a distinctive form of explanation in history, whose object was the meaning of human action and whose structure was narrative rather than deductive.

Neither side in this debate was able to claim a convincing victory, with the result that philosophers gradually lost interest in history and began to concern themselves more generally with the nature of human action. This interest, combined with a revival of nineteenth-century German hermeneutics, the study of texts in their social and cultural milieu, in turn revived interest among analytical philosophers in the writings of Hegel and Nietzsche. The impact of continental influences in philosophy, art criticism and social theory was considerable, and reintroduced a historical dimension that had been largely absent from twentieth-century analytical

philosophy. In particular, the formation of fundamental philosophical ideas began to be studied as a historical process. The Enlightenment came to be seen as a crucial period in the development of philosophy, and of modernity more generally, and with this understanding came the belief that the contemporary Western world is postmodern. In this way, social theory and the philosophy of culture in fact returned, albeit unawares, to the 'grand narrative' tradition in philosophy of history.

GORDON GRAHAM

HOBBES, THOMAS (1588–1679)

Introduction

Among the figures who were conscious of developing a new science in the seventeenth century, the Englishman Hobbes stands out as an innovator in ethics, politics and psychology. He was active in a number of other fields, notably geometry, ballistics and optics, and seems to have shown considerable acumen as a theorist of light. His contemporaries, especially in Continental Europe, regarded him as a major intellectual figure. Yet he did not earn a living as a scientist or a writer on politics. In 1608 he entered the service of Henry Cavendish, First Earl of Devonshire, and maintained his connections with the family for more than seventy years, working as tutor, translator, travelling companion, business agent and political counsellor. The royalist sympathies of his employers and their circle determined Hobbes' allegiances in the period preceding and during the English Civil War. Hobbes' first political treatise, *The Elements of Law* (1640), was not intended for publication but was meant as a sort of long briefing paper that royalists in parliament could use to justify actions by the king. Even *Leviathan* (1651), which is often read as if it is concerned with the perennial questions of political philosophy, betrays its origins in the disputes of the pre-Civil War period in England.

For much of his life the aristocrats who employed Hobbes brought him into contact with the intellectual life of Continental Europe. He found not just the ideas but also the spokesmen congenial. Perhaps as early as 1630 he met Marin Mersenne, then at the centre of a Parisian network of scientists, mathematicians and theologians that included Descartes as a corresponding member. It was to this group that Hobbes attached himself in 1640 when political events in England seemed to him to threaten his safety, causing him to flee to France. He stayed for ten years and succeeded in making a name for himself, particularly as a figure who managed to bring geometrical demonstration into the field of ethics and politics. His *De cive*, a treatise that has much in common with the *Elements of Law*, had a very favourable reception in Paris in 1642.

By the time *De cive* appeared, Hobbes had taught himself enough natural philosophy and mathematics to be taken seriously as a savant in his own right. He had also conceived the plan of producing a large-scale exposition of the 'elements' of philosophy as a whole – from first philosophy, geometry and mechanics through to ethics and politics. *De cive* would be the third volume of a trilogy entitled *The Elements of Philosophy.* These books present Hobbes' considered views in metaphysics, physics and psychology against the background of a preferred scheme of science.

Metaphysics, or first philosophy, is primarily a definitional enterprise for Hobbes. It selects the terms whose significations need to be grasped if the principles of the rest of the sciences are to be taught or demonstrated. Foremost among the terms that Hobbes regards as central are 'body' and 'motion'. According to Hobbes, the whole array of natural sciences can be organized according to how each treats of motion. Geometry is the first of these sciences in the 'order of demonstration' – that is, the science whose truths are the most general and on which the truths of all the other natural sciences somehow depend. Mechanics is next in the preferred order of the sciences. It considers 'what effects one body moved worketh upon another'. Physics is the science of sense and the effects of the parts of bodies on sense. Moral philosophy or 'the science of the motions of the mind' comes next, and is informed by physics. It studies such passions as anger, hope and fear, and in doing so informs civil philosophy. Starting from the human emotional make up, civil philosophy works out what agreements between individuals will form commonwealths, and what behaviour is required within commonwealths to make them last.

The behaviour required of the public in order to maintain a commonwealth is absolute submission to a sovereign power. In practice this means abiding by whatever a sovereign declares as law, even if those laws appear to be exacting. Law-abiding behaviour is required so long as, in return, subjects can reasonably expect effective action from the sovereign to secure their safety and wellbeing. With minor variations, this is the theme of all three of Hobbes' political treatises – the *Elements of Law, De cive* and *Leviathan*. Government is created through a transfer of right by the many to the one or the few, in whom an unlimited power is vested. The laws of

the sovereign power may seem intrusive and restrictive, but what is the alternative to compliance? Hobbes' answer is famous: a life that is solitary, poor, nasty, brutish and short. This conception of life without government is not based on the assumption that human beings are selfish and aggressive but, rather, on the idea that if each is their own judge of what is best, there is no assurance that one's safety and one's possessions will not be at the mercy of other people – a selfish few, a vainglorious minority or even members of a moderate majority who think they have to take pre-emptive action against a vainglorious or selfish few. It is the general condition of uncertainty, in conditions where people can do anything they like to pursue their wellbeing and secure their safety, that Hobbes calls 'war'.

1 Life

Hobbes was born in Westport, a parish of the town of Malmesbury in Wiltshire, England. His mother came from a yeoman family; his father was a poorly educated vicar who seems to have left his parish in disgrace, deserting his family after having come to blows with another clergyman early in Hobbes' childhood. Hobbes' uncle subsequently supported the family, and it was he who paid for Hobbes' university education. Hobbes was lucky to receive good schooling locally, and he showed an early talent for the classical languages.

In 1602 or 1603, Hobbes began study towards an arts degree at Magdalen Hall, Oxford. From his criticisms of the universities in his published writings, it is sometimes inferred that he disliked his college days, or at least that he disliked the scholasticism of Oxford at that time. (Scholasticism – the fusion of Christian with ancient Greek thought, especially the thought of Aristotle – dominated the curricula of the schools and universities of Europe in the sixteenth and early seventeenth centuries – see MEDIEVAL PHILOSOPHY.) Certainly he disliked the university curriculum in retrospect, as chapter 46 of *Leviathan* (1651) makes clear.

Hobbes completed his degree in 1608, and entered the service of William Cavendish, First Earl of Devonshire, as companion and tutor to his son. Although Hobbes was about the same age as the young Cavendish, he was put in charge of his purse as well as his education. He was the earl's representative at meetings of the Virginia Company, in which the Devonshire family had a considerable financial stake. He also accompanied the earl's son on a grand tour of the Continent in 1610, which allowed Hobbes to improve his command of French and Italian. According to some accounts, he also became acquainted then with criticisms of scholasticism current among Continental intellectuals.

It is unclear how long this grand tour lasted, but Hobbes had returned to England by 1615. At some point during these travels Hobbes seems to have met Fulgenzio Micanzio, the friend and personal assistant of the Venetian writer and politician Paolo Sarpi. He must also have met Marc Antonio de Dominis, who was involved in the translation of Bacon's writings into Italian and who also had connections with Sarpi (see BACON, F.). Hobbes' own contact with Bacon may have had its stimulus in the requests of the newly befriended Venetians for more details of the Baconian philosophy. The young Cavendish began a correspondence with Micanzio after returning to England in 1615. Hobbes translated this correspondence and through it would have been exposed to Sarpi's theory of the supremacy of temporal rulers rather than spiritual authorities. The theory went against the Papal interdict of 1606, which asserted Rome's right to overrule the decisions of local monarchs and which had encountered much criticism in England. There are apparently strong echoes of this anti-Papal line in Hobbes' own writings.

During his first twenty years of service to the Devonshires, Hobbes seems to have spent his free time immersed in classical poetry and history. His employers had a good library, and Hobbes made use of it. The first fruit of this regrounding in the classics was a translation into English of Thucydides' *History of the Peloponnesian Wars*, published in 1628. Hobbes believed that Thucydides had lessons for those who overvalued democracy and did not see the strengths of monarchy, and it may have been the Petition of Right of 1628 that led to the publication of the translation. The Petition called on Charles I not to levy taxes without the consent of Parliament, not to imprison subjects without due cause, not to billet soldiers in private homes and not to put civilians under martial law. This sort of challenge to the prerogatives of a monarch is opposed in all of Hobbes' political writings, and the opposition is foreshadowed in the translation of Thucydides.

In 1628 Hobbes chose history as the medium for a political message. Later, in writings like *Leviathan*,

he thought science or philosophy was the better vehicle. In writing history it is possible for the conventions of the genre to interfere with the communication of wisdom; in writing science, he came to believe, the communication of wisdom is assured, if the audience is prepared to pay attention and able to follow a demonstration. He struggled throughout his intellectual life with the problem of combining political rhetoric with political science, and some of his best writings are experimental solutions to this problem. The translation of Thucydides is important as the first of many such experiments.

The year 1628 was a kind of turning-point in Hobbes' career. Apart from publishing the translation of Thucydides, he had to contend with the death of the second earl at the age of 43, resulting in his loss of employment with the Devonshires. Hobbes took up a new post in the house of Sir Gervase Clifton, not far from Hardwick Hall, the home of the Devonshires. Once again he was engaged as a companion on a grand tour, this one lasting from 1629 to 1631. During this journey Hobbes looked for the first time at Euclid's *Elements*, and fell in love with geometry. There is plenty of evidence in Hobbes' writings that he regarded Euclid's book as one of the supreme examples of a scientific presentation of a subject. Perhaps also during this second journey to the Continent Hobbes was present at a discussion among some well-educated gentlemen about the nature of sense-perception, in which it emerged that none of the participants could say what sense-perception was. Both episodes are significant, because they seem to mark the beginning of Hobbes' transformation from man of letters to man of science.

Perhaps the stimulus for the change was not the second grand tour alone. After his return, Hobbes went back into the service of the Devonshires and became tutor to the young third earl. At about the same time, he came into contact with a branch of his master's family who lived at Welbeck, near Hardwick Hall. The Welbeck Cavendishes were interested in science. The Earl of Newcastle is known to have sent Hobbes on an errand to London to find a book of Galileo's in the early 1630s. The earl's younger brother, Charles, had an even greater interest in science: he acted as something of a patron and distributor of scientific writings. Hobbes was one of those who looked at and gave his opinion of these writings. Charles Cavendish also had contacts among Continental scientists, including Marin Mersenne, a friar in Paris who was at the centre of a circle of scientists and philosophers that included Descartes.

Hobbes' scientific development continued when he embarked with the third earl on yet another grand tour from 1634 to 1636. During this journey he is supposed to have met Galileo in Italy, as well as Mersenne and some members of his circle in Paris in 1636. Hobbes had probably become acquainted with Mersenne five years earlier on the second tour. It is said that on the third grand tour Hobbes was much preoccupied with the nature and effects of motion, and that he started to see for the first time how many natural phenomena depended upon it.

On his return to England, Hobbes kept up with some of the scientific work being produced in Mersenne's circle. Descartes' *Discourse and Essays* were published in 1637. Hobbes was sent a copy and seems to have made a careful study of the first of the *Essays* – on optics – perhaps taking time to write something of his own on the same subject. He was not keeping abreast solely of scientific ideas. Through his association with a circle of clergy, lawyers and aristocrats at Great Tew, near Oxford, he was able to follow the continuing debates surrounding the troubles of Charles I. In 1634 the king started to raise funds for a navy by a ship-money tax levied county by county. This tax-raising met opposition, particularly in non-coastal counties. Besides the ship-money dispute, Charles I had to reckon with the consequences of trying, in 1637, to bring the Scottish Presbyterian prayer book into line with its Anglican counterpart. This provoked a National Covenant in Scotland expressing wholesale opposition to ecclesiastical innovations from England. In 1639 and 1640 the Scots raised armies to back up their opposition, and Charles was forced to recall a parliament he was used to ruling without, and which was extremely hostile to him. When Parliament acted against Stafford, a minister of the King associated with the Earl of Newcastle, Hobbes worked on arguments that could support the royalist position in parliamentary debates. The arguments were produced in a treatise, *The Elements of Law* (1640), not intended for publication but which, in fact, contains much of the doctrine of Hobbes' political philosophy. Fearing that he would be prosecuted for giving the royalists their arguments, he fled to Paris and joined the circle of philosophers and scientists around Mersenne.

Some years after 1640 Hobbes wrote that he had recently conceived a plan for expounding, in three parts, the elements of philosophy or science in general. His exposition would begin with the nature of body and the elements of what we now call physics. It would go on to discuss human nature, in particular perception and motivation, and the third part would be a discussion of moral and civic duty. Perhaps he had already drawn up this plan, and even executed some of it, by the time he reached Paris. What *is* certain, however, is that the first part of the exposition to be published was the last of the three

in his outline – the part on morals and politics. Hobbes called this part of his exposition *De cive* and published a very limited edition of it in Latin in 1642.

Hobbes seems to have enjoyed good relations with most of Mersenne's circle. He was at odds with Descartes, however, whose *Meditations* he criticized in a set of 'Objections' – the anonymous 'Third Set' (see DESCARTES, R. §§4, 6). From 1641 until Mersenne's death in 1648, Hobbes applied himself to the composition of the rest of his three-part exposition of the elements of science. He produced some of the material for the first part of the exposition – on body, the part published in 1655 as *De corpore* – and took up topics that would later occupy the middle part of the exposition. In 1643 he wrote a critical commentary on *De mundo*, a treatise written by Thomas White (another Englishman in Paris at that time) which was sympathetic to scholasticism. In 1646 Hobbes composed some arguments about the respects in which freedom is compatible with causal necessitation in nature, arguing once more on this occasion against scholastic positions. He suffered a serious illness in 1647 and almost died. While on his sickbed he rebuffed an attempt by Mersenne to convert him to Roman Catholicism.

In 1648 Mersenne died and the philosophical and scientific activity that had gone on around him ceased to have a focal point. Hobbes now had a place among the royalists in exile, but he was on poor terms with churchmen around the exiled Charles II in Paris and was receiving his pay rather irregularly. By the autumn of 1649 he seems to have formed the intention of going home.

Leviathan, in which Hobbes attempted to derive from his now well-worked-out political principles the right relation of Church to state, was written at the end of the 1640s, when church government in England began to run on lines of which he approved and at a time when the influence of bishops in the English royal court-in-exile in Paris was, in Hobbes' eyes, too great. In any case, the fact that the theory in the book vindicated Cromwell's policy on church government does not mean that it was a partisan work in favour of Cromwell, calculated to ease Hobbes' return to England. If that had been so, Hobbes would not have made a special presentation copy for the future Charles II. Instead, it seems that the doctrine in *Leviathan* favoured the concentration of all authority in any *de facto* sovereign power, whether republican or royal. To the Paris royalists, mostly strong Anglicans in favour of political powers for bishops, the new book was highly offensive.

By the end of 1651 Hobbes was back in London and all three statements of his political philosophy were available in some form in English. These political works were widely known before his exposition of the elements of science was complete. Even though *De cive* had been planned to complete a sequence of three treatises on these elements, it did not depend on the other treatises in order to be understood, and it has always had a readership of its own. When the other two works in the sequence appeared in the 1650s, they did not match *De cive* in quality. The treatise on which Hobbes had been working longest was the opening work of the sequence, *De corpore*, published in 1655. In it Hobbes tried to show how the mature sciences of geometry, mechanics and physics were concerned with the effects of different kinds of motion in matter. Politically motivated critics soon exposed the weaknesses in the mathematical sections of the book, and Hobbes' attempt to vindicate his work involved him in years of fruitless polemic. *De homine*, the second volume of his *Elements* and undoubtedly the least well-integrated of the three, was published in 1658. It was never widely read, and a modern English translation of it has only recently appeared.

In 1660 the monarchy was re-established in England, and on the coat-tails of Charles II there returned to political power many who regarded Hobbes as a traitor to the royalist cause. Charles himself was not hostile, however, and other influential people were also well-disposed towards him. Nevertheless, in 1666 and 1667, Parliament came close to passing a bill outlawing Christian heresy and atheism, and *Leviathan* was specifically investigated as a source of heretical and atheistic views. The danger of imprisonment and exile did not dissipate until the end of the decade. The threats to Hobbes were reflected in additions that he made to a Latin edition of his works published in Holland in 1668. He argued that punishment for heresy was illegal under English law and that his materialism was compatible with Christian faith. Two significant works from the 1660s were applications of his political philosophy. There was a history of the English Civil War, *Behemoth* (1668), and the *Dialogue between a Philosopher and a Student of the Common Laws of England*. By the time these works were composed, Hobbes was not permitted to publish, and though he busied himself with some translations of the classics and a few other minor writings of his own in the 1670s, he had come almost to the end of his working life.

In his ninetieth year, Hobbes returned to physics. His *Decameron Physiologicum* (1678) restates some of the methodology and principal results of the physical sections of *De corpore*. For the preceding three years Hobbes had divided his time between the two Devonshire houses of Chatsworth and

Hardwick Hall. In December 1679 he died of a urinary complaint. His remains are buried in a small parish church near Hardwick Hall.

2 Science and human improvement

Hobbes' writings are those of an advocate and practitioner of a new science, a system of knowledge of causes that could, as he believed, greatly benefit human life. Yet he formed his ideas during a period when human intellectual powers, including the ability to develop science, were commonly thought to be limited. According to some theories prevalent in the late sixteenth and early seventeenth centuries, the whole human race was involved in a quite general and unstoppable process of natural decay, so that all the best achievements of human beings belonged to a long-lost golden age. It was a way of understanding things that was consistent with, if not inspired by, the Biblical story of the Fall of Adam and Eve, and the loss of paradise. According to some understandings of that story, Adam's expulsion from paradise cost him not only a life of ease in harmony with God and the rest of nature, but also the gift of a natural insight into the natures of all the things he could name. Regaining the knowledge of those natures might never be possible. In France, in the late sixteenth and early seventeenth centuries, recently popularized Greek sceptical arguments against dogmatism reinforced the view that human intellectual possibilities were limited. The arguments were directed not only against the traditional learning of the schools but against the idea that any human learning – even untraditional or anti-traditional learning – could amount to a system of genuine knowledge. Hobbes' philosophy of science stands in opposition to much of this gloomy theorizing. It stands in opposition to philosophical scepticism, to the theory of the decay of nature as applied to the human intellect and, to a lesser extent, to pessimistic interpretations of the intellectual costs of the Fall.

Although Hobbes had close friends and intellectual influences among French thinkers who took sceptical arguments seriously, there is little if any solid evidence in his own writing that he studied these arguments closely or took their conclusions to heart. He seems never to have doubted the soundness or scientific status of Euclid's geometry, and he was an early enthusiast for the applied mathematics of Copernicus, Kepler and GALILEO. He was also proud of the judgment of some early readers of *De cive* that this book ushered in a demonstrative science of ethics. Hobbes called himself the inventor of civil science and thought that his politics deserved a place alongside Galileo's mechanics. The newly founded natural and moral sciences he regarded not only as great intellectual achievements, but as distinctively modern ones. Contrary to the theory of the decay of nature as applied to the human intellect, natural and civil science had not ceased with the ancients, but had only properly begun with the work of the mathematical astronomers and his own work in *De cive*. However, Hobbes also held that human beings were badly adapted by nature to do science of this kind, and that they had to work very hard to be capable of it. He thus disagrees both with the Cartesian idea that God benignly creates us with the ingredients of science latent in our minds *and* with the Aristotelian idea that knowledge of the natures of things is the unforced and inevitable by-product of repeatedly looking and seeing. To a very significant extent, according to Hobbes, our capacities for natural science are made by us rather than given to us. This position concedes something to both scepticism and the theory that life will always be difficult for Fallen Man. Although according to Hobbes sceptics are wrong to claim that we are incapable of science, they are right in insisting that we lack native scientific ability. They are also right to doubt that human beings are capable of an exalted sort of knowledge, the knowledge of what necessitates effects. For Hobbes, the scientific knowledge of which we are capable rarely rises to the level of knowledge of how effects *must* have been brought about, and it is not taken to extend to all effects. Again, although Hobbes believed that the scientific achievements of his contemporaries and himself were important, and that the then nascent sciences of nature and politics would develop further, he did not, with Descartes, suppose that we might one day complete science. Finally, while he claimed that even in their undeveloped state the sciences had delivered considerable benefits, Hobbes did not expect a more developed science to be the answer to all our problems. Like Bacon he believed that science could not entirely repair the Fall, that it could only act to relieve some of what was bad in human existence. Whatever one did, life would continue to have 'incommodities', but with the development of science life would contain fewer of them.

Science is not, then, for Hobbes, a means of regaining Eden. At best, it is our only way of cutting the costs of losing Eden. In paradise, Adam enjoyed the gift of immortality in conditions of ready abundance. Everything he could properly want was there for the taking. Punished for eating from the tree of knowledge Adam lost his immortality. He lived, as Hobbes puts it in *Leviathan*, under a death sentence ([1651] 1839 III: 438). Adam also lost the abundance of Eden. Banished to a place outside paradise, he had for the first time to work for a

living, and to do so in a relatively inhospitable environment. Had they stayed in Eden, Adam and Eve would not have reproduced their kind continually or perhaps at all ([1651] 1839 III: 440). When they left they came under a necessity to multiply that worsened the life of their kind still further. Adam's descendants, the rest of humanity, inherit from him not only their mortality but also life outside Paradise. Thanks to Adam's transgression, human beings in general live in a world that demands ingenuity and hard work for survival. And thanks to human carnality, Adam's descendants have to eke out a living in the company of, and often in competition with, many others of their own kind. These facts of life do not make it easy to do well. In order to flourish in a sometimes harsh physical environment people have to know which effects they observe are beneficial and which are harmful, and they have to learn to reproduce the beneficial ones and prevent, or at least avoid, the harmful ones. In order to flourish in a heavily populated environment people have to know how to co-operate with one another. Moreover, these problems have to be coped with simultaneously.

As things naturally are, however, the problems are too great for creatures like us. For, being descended from Adam, human beings inherit the cognitive and conative capacities of someone designed to live in paradise, not the harsh world outside. If things had gone according to God's plan, Adam would not have needed to get causal knowledge of nature; he could have satisfied himself with contemplating the diversity and order in nature. Adam would not have had to make nature supply his needs. He would not have had to cope with overpopulation and the demands of co-operation. Made for a life without problems, Adam lacked the means – that is, the science – to solve problems. As Hobbes points out in *Leviathan*, there is no evidence in scripture that Adam had the vocabulary to do science (*Elements of Law* [1651] 1839 III: 19), and yet without the vocabulary to do science we should be no better off than savages or beasts (1640 pt I, ch. 5: iv; 1658 ch. 10: ii, iii). Either people reconcile themselves to living at the mercy of the elements and of one another – Hobbes thought that this was the course taken by Native Americans – or else they take the long and difficult road to a better life through science. Neither the better life nor the means to it are out of bounds to human beings, but both involve a kind of human reform. To get access to the degrees and varieties of motion that are required to understand nature, human beings need to acquire concepts more general and universal than those for everyday experience, and they need to apply principles involving these concepts in tasks of measurement and manufacture. To solve the problems of peaceful co-operation they need to be able to recognize the consequences of everyone's trying to get what they want. This means more than knowing what moral precepts to follow. It means being able to see what overall good the moral precepts promote – something revealed by Hobbes' civil science – and adjusting one's practical reasoning to the pursuit of that good rather than something nearer and more gratifying.

Although human beings cannot live well without science, science does not come naturally to them. Science depends on the ability to impose names aptly, to join names into propositions, and to join propositions into syllogisms, but not even these prescientific linguistic skills are natural to people. People come into the world being able at most to form sensory representations of things, and to learn from experience. But experience is a far cry from science. In its raw state experience is either a disorganized stream of representations or else a coherent sequence. If it is a coherent sequence, then, according to *Leviathan*, it is 'regulated' by some design or plan, or by curiosity about an observed body's effects ([1651] 1839 III: 13). Regulated in either way, a train of experience is only regulated as past experience allows it to be. Going by its past associations of observed phenomena, the mind will focus on a means to some goal or purpose in hand, or will suggest properties it is accustomed to conjoin with other properties it is now curious about. Once there are words for the things of which the mind has conceptions – words that can be used to signify the elements of experience – the possible ways of juxtaposing the words significantly, of analysing them and drawing consequences, introduce ways of ordering the elements that are not foreshadowed in previous experience.

New ways of regulating thought become possible because, for one thing, it is not necessary for a body spoken about to be present or remembered in order for a train of thought about it to be created. The train of thought can be generated instead by exploiting logical relations or analytic truths to get from one speech or thought to another. Reasoning can thus introduce new possibilities of combining things given separately in experience; it can also introduce ways of taking apart or separating things confounded in experience. Nor are the possibilities confined to the powers of one man's reasoning. Speech enables investigation and reasoning to be carried on co-operatively, and allows one person's explanations to be tested for clarity and coherence by others. The reasonings or explanations of one person can be preserved over time and made the model for those of many other people. A method

can even be extracted from the findings of the most successful or conclusive pieces of reasoning, so that conclusive reasonings and explanations – in a word, science – can deepen and spread.

Hobbes believed that science as a whole could be divided into two principal parts, one concerned with natural bodies, the other with bodies politic. Each part of science arrives by reasoning at the causes of the properties of its subject matter; and demonstrates effects, with a view to making the relevant subject matter useful and beneficial to human beings. But the two types of bodies are very different from one another, and pose different scientific problems. Natural bodies are not made by us, and so the causes of their properties have to be worked out by reasoning from the appearances they present. Since the maker of natural bodies, God, is omnipotent and able to bring about effects in more ways than can be dreamed of in our explanations, only possible causes can be assigned to the appearances they present. Bodies politic *are* made by us – they are human artefacts and so at least in principle we can be certain of the causes of *their* properties. But the philosophical challenge they present is not primarily that of knowing their causes: it is that of knowing how they should be designed so that they last. This means setting out rules by which those involved in the commonwealth – those in government on the one hand and those subject to government on the other – can conduct themselves so that civil peace is ensured. It is doubtful whether the statement of these rules is really a science of a kind of body, as is natural science, and probably the differences between natural and civil science are to be taken more seriously than the supposed analogies. Hobbes claims that civil science is not only more certain, but more widely needed, and more accessible than natural science. On the other hand, natural science is the more fundamental of the two parts of science: its explanatory concepts are more general than those of civil science and are needed if a scientific understanding of the passions and actions of agents in civil life is to be acquired from the 'first and few' elements of science as a whole.

3 The elements of philosophy: logic and metaphysics

The relative positions of the two parts of science – natural and civil – are reflected in the organization of Hobbes' trilogy on the elements of philosophy. The first volume, *De corpore*, expounds first philosophy, geometry, mechanics and physics. It is followed by *De homine*, which is half optics and half psychology; this volume in turn is supposed to prepare the ground for the exposition of the elements of ethics and politics in *De cive*.

The account of the 'elements' of science starts in *De corpore* with chapters on the ways in which philosophy depends on names, propositions and methods of reasoning. For Hobbes, logic is nothing more than the right ordering and joining of significant propositions into chains of reasoning. Propositions in turn are no more than coherent concatenations of names with significations of different extents. A name signifies an idea – whatever idea it conveys in the context of a speech to a hearer. But the idea is not what the name refers to or stands for: it refers to or stands for an object. To make a proposition, names have to be put together coherently, and coherent concatenations are concatenations of the same category of name – names of bodies with names of bodies, names of names with names of names. The 'extent' of the signification of a name has a bearing on the truth of propositions. The signification of a proper name will extend to an individual, that of a universal name – 'man', 'horse', 'tree' – to each of a plurality of individuals. In the propositions of natural science, names are universal names of bodies. Truth in the propositions of natural sciences is a matter of the inclusion of the extent of a universal subject-term within the extent of a universal predicate-term. Demonstrations are chains of syllogisms, and syllogisms are the stringing together of trios of propositions that share appropriate subjects and predicates. In a sense, then, logic is a technique for working out the consequences of relations between the significations of universal names or their extents. There are also methods belonging to logic for analysing the significations of names, and for arriving at the most general of these significations from a starting point in everyday universal names. Logical analysis of this kind is what is required to locate the terms fundamental to the various branches of science; it also has a role in making scientific questions amenable to resolution. Metaphysics or first philosophy sets out, ideally by means of definitions, the concepts necessary for conducting fruitful enquiries concerning natural bodies and for communicating the results. The relevant concepts include those of body, motion, time, place, cause and effect.

Hobbes composed no full-scale treatise on logic, and no work of his is concerned with metaphysics alone. *De corpore* contains the nearest approximation to a full first philosophy, and even here he is not entirely clear about the borderline between that 'prior' science and geometry. There is a chapter on 'syllogism', but it is not comprehensive and its relation to traditional syllogistic is never spelled out. As for the chapters on first philosophy, they are more significant for what they deny than for what they affirm. They deny that it makes sense to study

'being' in the abstract; they deny that species or genera are things; they deny that 'substance' can mean something very different from 'body'; and they deny that other predicables are more than varieties of sensory appearance caused by bodies. In short, they deny much standard Aristotelian doctrine, including the doctrine defining the subject matter of metaphysics itself – the doctrine that metaphysics studies being *qua* being. As will become clear, the chapters on first philosophy can also be understood to register disagreements between Hobbes and some of the *moderns* – Descartes and Gassendi, among others.

Hobbes' first philosophy starts with a thought experiment. He imagines that the external world has been annihilated – all that remains is a single thinker and the traces in memory of the world he previously sensed and perceived. Hobbes claims that the disappearance of the external world would not take away conditions for thought or reasoning, even about the physical world. The annihilation of the world would not even *alter* conditions for such thought and reasoning, since the medium of thought and reasoning is never things themselves but only appearances or phantasms. Hobbes thinks that the annihilation of the external world leaves only the mind and its phantasms in existence. There is no third world of things that exist outside the mind but outside the physical world as well. So Hobbes denies that there exist without the mind abstract natures such as Descartes claims to discover in Meditation V; and, contrary to Gassendi in the *Syntagma*, he does not think that space and time are real independently of the mind. He derives the idea of space from the memory images or phantasms presenting things as if from outside the mind. He derives the idea of time from imagined motion, from succession without existence. He derives the idea of an existing thing from the imagination of an empty space suddenly getting an occupant. Existence is thus restricted to existence in space, which is in turn identified with corporeal existence. These resources allow for only a straitened conception of cause or power, and certainly not for an Aristotelian conception. There are no forms or purposes in nature; but the makings of a conception of efficient cause are available, and that is the only sense of 'cause' recognized by Hobbes' first philosophy.

Most of the concepts that Hobbes thinks are needed for natural science have now been indicated. In Part Two of *De corpore*, after defining 'time' and 'place', he thinks he is in a position to define 'body' and its most general accidents. He then deals with magnitude or real space-occupation, and the spatial relations of continuity and contiguity. Against this background he defines 'motion', and in terms of motion the ideas of length, depth and breadth. After the three spatial dimensions are explicated, he defines quantitative identity and difference for motions and bodies, and then discusses the conditions of qualitative difference between bodies over time. He goes on to consider the causes of qualitative change, concluding with a demonstration of the thesis that all change is motion, that motion is the only cause of motion, and that power (*potentia*) is nothing but motion in so far as it is a cause of motion.

Definitions dominate Hobbes' first philosophy and, officially at least, their purpose is to fix ideas necessary for the business of science proper. Hobbes thought that the mark of a prescientific branch of learning was controversy, and he traced controversy to a failure to define terms and to proceed in orderly fashion from definitions to conclusions. The task of first philosophy is to provide insurance against controversy. It does not do this by coming up with substantive truths that command assent. Instead, Hobbes describes first philosophy as a necessary *preliminary* to the demonstration of substantive truths, where demonstrator and learner are put on one another's wavelength and attach the same significations to their terms, but where their agreement is terminological rather than doctrinal. As Hobbes puts it in the *Six Lessons*, 'he that telleth you in what sense you are to take the appellations of those things which he nameth in his discourse, teacheth you but his language, that afterwards he may teach you his art. But teaching of language is not mathematic, nor logic, nor physic'.

That 'the teaching of language' underdescribes what Hobbes does in practice in stating his first philosophy, and that it suppresses entirely the revisionary character of some of his definitions when compared with Aristotelian ones (and so the controversial nature of the devices that are supposed to pre-empt controversy), should already be clear. But, up to a point, Hobbes' first philosophy is genuinely unassuming. It takes for granted no exotic powers or substances, God included, and it postulates no exotic human capacities for acquiring the concepts that are the key to natural science. The point is not just that Hobbes keeps the relevant concepts to a small number, so that he is economical in the concepts he uses and also in his assumptions about the types of real things there have to be for these concepts to be applicable. Hobbes' first philosophy is also *naturalistic*. Nothing supernatural is assumed to exist in order for natural science to be acquired; indeed, nothing besides matter in motion is postulated. What remains after the annihilation of the world in Hobbes' thought experiment is not the immaterial self of Descartes, but the corporeal body or perhaps the brain, and the motions conserved in its internal parts from past impacts of the external world on the sense-organs.

The denial of immaterialism in Hobbes' first philosophy is anticipated in his Objections to Descartes' *Meditations*. An objection that Hobbes directs at Meditation II sets the tone (see DESCARTES, R. §5). He accepts that from the fact that I am thinking it follows that I exist, but he wonders whether Descartes can properly conclude, as a corollary, that the I is a mind or an intelligence or a thinking thing. For all the *Cogito* shows, Hobbes says, the I could be corporeal. And not only does the *Cogito* leave open the possibility of the I being corporeal, he goes on, the later wax argument actually *shows* that the I is corporeal:

> We cannot conceive of jumping without a jumper, or knowing without a knower, or of thinking without a thinker.
>
> It seems to follow from this that a thinking thing is something corporeal. For it seems that the subject of any act can be understood only in terms of something corporeal or in terms of matter, as the author himself shows later [in] his example of the wax: the wax, despite the changes in its colour, hardness, shape and other acts, is still understood to be the same thing, that is, the same matter is the subject of all of these changes.
>
> (Hobbes, *The Third Set of Objections to Descartes' Meditations* 1641)

Descartes' reply concedes that acts need subjects, that it is a *thing* that is hard, changes shape and so on, and also a *thing* that thinks, but he insists that 'thing' in this sense is neutral between the corporeal and the spiritual. He insists, too, that he is non-committal about the nature of the thing that thinks in Meditation II, a claim borne out by his responding agnostically in Meditation II to the question of whether he might be a structure of limbs or a thin vapour. If Hobbes misses that, it may be because he misunderstands the rules of the method of doubt. While implementing the method of doubt, Descartes does assume rather than prove that there is no body for the thinking thing to be or for the thought to inhere in. But this is not a case of begging the question, for the belief in the existence of bodies is reinstated in Meditation VI, and with that the question of whether the subject is essentially immaterial or material.

Hobbes comes at Descartes' immaterialism from another, more revealing direction when he tries to suggest that it is not needed to underpin the distinction between imagination and conception by the mind. In his fourth objection, Hobbes equates imagination in Descartes' sense with having an idea of a thing, and conception in Descartes' sense with reasoning to the conclusion that something exists. Descartes already agrees that imagination is a partly corporeal process resulting from action on the sense organs, but his text suggests that conception by the mind is an altogether different operation. Hobbes puts forward a suggestion that allows the explanation of conception and imagination to be linked, without the postulation of immaterial things. He proposes that reasoning is the process by which labels attached to various things are concatenated into sentences according to conventions agreed by humans.

> Reasoning will depend on names, names will depend on the imagination, and imagination will depend (as I believe it does) merely on the motions of our bodily organs; and so the mind will be nothing more than motion occurring in various parts of an organic body.
>
> (*Objections* 1641)

The compatibility of this proposal with mechanistic explanation appeals to Hobbes; but Descartes raises some powerful doubts about Hobbes' idea that names alone come into reasoning. Contrary to Hobbes, Descartes takes it that reasoning is a matter of linking together the significations of names, not just the names themselves, and also that the significations of some names cannot be imaged.

As in the case of his objection concerning the subject of the thinking, which seems to overlook the constraints of the method of doubt, Hobbes' objection to Descartes on imagination and conception seems to miss the point. Descartes is not trying to explain the workings of the faculties that result in science, only to find that he has to explain them on immaterialistic principles. He is trying to show that science is possible, that real knowledge of the physical world is possible, because not all of our faculties can coherently be held to be unreliable. Conception by the mind is a case in point. It cannot be held to be unreliable, because it is autonomous and independent of unreliable sense-perception. Hobbes does not see that it is the objectivity of conception rather than the process of conception that Descartes is concerned with. And doubting the objectivity of conception himself, Hobbes does not seek to reconstruct conception as reasoning that might be guaranteed to lead to true conclusions; he wants only to reconstruct it in ways that will not multiply entities beyond those required by mechanistic explanation. The point is that a proof of the objectivity of the conceptions arrived at by science may legitimately be demanded of a metaphysics, and Hobbes' metaphysics does little if anything to meet the demand. The metaphysical economy of materialism will not impress someone who is sceptical of the existence of the external world: the undeniability of the *Cogito* might. One cost of Hobbes' naturalistic approach is that it never

attempts the task of legitimizing the scientific enterprise in general, and is probably incapable of doing so.

4 Geometry, optics and physics

First philosophy is a preliminary to natural science proper, and the first of the natural sciences is geometry. Geometry is a natural science for Hobbes, because it studies the effects of moving bodies. It studies the properties of straight lines, for instance, and straight lines are the effects of the motion of a small material thing – a point. He rejects the idea that the geometrical point is an abstraction distinct from some small material mark or other. Being a body, a geometrical point is divisible and not, as Euclid had it, 'that which hath no part'. A point could no more lack quantity than a line could lack breadth and be constructed by motion. The bodies whose motions geometry studies may not have much quantity, and the quantity may not be relevant to what is being demonstrated of them, but they are bodies all the same. Though geometry is a science of bodies, it is also in a sense an a priori certain science, as physics is not, for the effects are produced by us, and we know in advance by what means they are produced. In this, Hobbes believed, geometry is like politics. In a sense, too, geometry is a very basic science – basic not in the sense that the objects it studies are higher or more real than those in nature, but in the sense that it studies bodies and motion at a very high level of generality, with much that is specific about the bodies left out of account. Hobbes thinks that geometry is also basic in another sense, for its methods of demonstration and analysis are the inspiration for the methods of the other demonstrative sciences.

Hobbes was self-taught in mathematics, and his friend and biographer, John Aubrey, says he did not encounter Euclid until he was middle-aged. Nevertheless, he was taken seriously by very able geometers in Mersenne's circle, and is even credited with inspiring a proof by Roberval of the equality of arcs of a parabola and an 'Archimedean' spiral. He is much better known, however, as a mathematical failure whose attempts at expounding geometry in *De corpore* were ridiculed by the English mathematician John Wallis. Wallis' attack was motivated by a wish to discredit the anticlerical passages in *Leviathan*, and its attack on the universities. In correspondence with Huygens, Wallis said that Hobbes 'took his courage' from mathematics, and so it 'seemed necessary for some mathematician to show him how little he understands'. Wallis' attack succeeded – it focused on Hobbes' doomed enterprise of producing a quadrature of the circle – and was made the more effective by Hobbes' persistent refusal to concede errors.

Although the geometrical parts of *De corpore* were supposed to present some new results, Hobbes did not claim any great stature for himself in geometry. In optics, on the other hand, he regarded himself as a major figure. It was certainly a subject he turned to early in his transformation from man of letters to man of science. As early as 1636, optical questions were featuring in his correspondence with the Earl of Newcastle, and the treatment of the sensible qualities was mechanical: 'whereas I use the phrases, the light passes, or the colour passes or diffuseth itselfe, my meaning is that the motion is onely in the medium, and light and colour are but the effects of that motion in the brayne'. Perhaps more accurately, these effects were supposed to be the effects of the motion of the medium transmitted to the animal spirits in the brain.

Exactly how early Hobbes arrived at his conception of the workings of light is not entirely clear. A short treatise dated to 1630 and originally attributed to Hobbes has been claimed by some scholars to be the work of someone else in the Cavendish circle. It contains doctrines different from writings that are more certainly ascribed to Hobbes, and which probably belong to the 1640s: the *Tractatus Opticus* I and II. It also contains as 'principles' formulations that these later optical writings present as mere hypotheses. Whether the writings of the 1640s represent only a change of mind or whether they are Hobbes' first extended publications in optics, they show him adopting a mediumistic theory of the propagation of light based on the idea of continuously expanding and contracting light sources. These displace contiguous parts of an ethereal medium of uniform density and set up a chain reaction to the eye. A resistance in the eye caused by a countervailing motion from the brain produces a phantasm of a luminous object – that is, in Hobbes' terminology, light. Light is propagated instantaneously, as both luminous object and medium expand simultaneously. The account does without the postulation of an emission by luminous objects of species or replicas of themselves which subsequently inform the senses and permit perception. Instead, luminous objects illuminate by radiation: they, so to speak, send out rays or, more precisely, displace the medium along paths called 'rays'. In their passage from luminous objects to the eye, rays are supposed to describe parallelograms. Hobbes used the properties of other geometrical figures described by rays of light passing through different densities to account for refraction. Colour he regarded as light perturbed by the internal motions of rough or coarse bodies on its way to the eye. The differences between the colours on the

spectrum from blue to red he accounts for as the product of refraction plus restraint or reinforcement of the lateral motion of rays of light that goes with refraction.

At no point in the process that starts with the motion of the luminous objects and ends in the production of the phantasm does Hobbes depart from a mechanical model of the causes of sense-perception. His mature theory of optics is through and through an account in terms of matter and motion. But between the *Tractatus Opticus I* and the *Tractatus Opticus II*, he seems to have revised his ideas about the organs of sensory perception. Phantasms are said to come from the heart, rather than to result from the clash of incoming motions with motions from the brain. By 1646, when Hobbes produced *A Minute or First Draught of the Optiques*, the most polished of his optical treaties, the main lines of his doctrine were settled. In addition to material on light and its propagation, refraction and reflection, there are accounts of various kinds of sensory error.

Physics, understood as the theory of the causes of appearances to sense and of the nature of the objects of sense, is in part an offshoot of optics. It is expounded at the end of *De corpore*. By an 'object' of sense Hobbes means an external body that registers in experience as being the subject of certain qualities, and that sets off the process culminating in an 'act of sense'. The object of sense is not an idea or a sense-datum or a mental image, though such a thing may be the medium in which the object of sense is registered. The greatest of the objects of sense is the world itself, as registered from some point within it. But only a few intelligible questions can be asked about the world, and these cannot be conclusively answered. One can ask whether it is of finite or infinite magnitude, whether it is full or contains empty space, and how long it has lasted. Only the second of these questions is open to a scientific answer, and even then only to a probable conclusion, while the others are for lawfully appointed churchmen to discuss. Hobbes thinks that probably there is no vacuum, that the world is full, but that some of the bodies that make it up are invisible: thus the ether and 'the small atoms disseminated through the whole space between the earth and the stars'. He adopts Copernican and Galilean hypotheses in chapter 26 of *De corpore* to explain the order, motion and relative position of the planets. He also infers explanations of, among other things, the passage of the seasons, the succession of day and night and 'the monthly simple motion of the moon'.

Hobbes goes on to consider the bodies between the earth and the stars. Foremost among these is 'the most fluid ether', which he proposes to regard as if it were first matter. He supposes that its parts only receive motion from bodies that float in them, and impart none of their own. The bodies in the ether are supposed to have some degree of cohesion or hardness and to differ from one another in shape, figure and consistency. Any more specific hypotheses about them Hobbes adopted only to explain particular phenomena. He is, however, willing to venture that many such bodies are 'unspeakably little' or minute, since God's infinite power includes a power infinitely to diminish matter. Assumptions about intersidereal bodies inform his theories of the phantasms appropriate to the different senses, not only light but also heat, sound and odour.

5 Ethics

After *physics*,' Hobbes writes in chapter 6 of *De corpore*, 'we must come to *moral philosophy*; in which we are to consider the motions of the mind, namely, *appetite*, *aversion*, *love*, *benevolence*, *hope*, *fear*, *anger*, *emulation*, *envy* &c what causes they have and of what they be causes'. The use of the term 'moral philosophy' for the doctrine of the motions of the mind is unfortunate; elsewhere Hobbes says that the precepts of his natural law doctrine add up to a moral philosophy. 'Ethics' is another label he sometimes uses, and it is preferable. The reason ethics comes after physics is that the motions of the mind 'have their causes in sense and imagination, which are the subjects of physical contemplation'. What Hobbes means is that when a body registers in a sensory representation – when, for example, a person sees something – the thing imparts motion to the innermost part of the organ of sight. One effect of the motion is to set up an outward reaction which produces visual experience. But there can be a further after-effect. As Hobbes puts it in chapter 8 of *Elements of Law*, the 'motion and agitation of the brain which we call conception' can be 'continued to the heart, and there be called passion'. The heart governs 'vital motion' in the body, that is the circulation of the blood. In general, when motion derived from an act of sense encourages vital motion, the sentient creature experiences pleasure at the sight, smell or taste of the object and is disposed to move its body so as to prolong or intensify the pleasure. If the object of the pleasure is at a distance, then the creature will typically move towards it. There is a symmetrical account of displeasure. This is an after-effect of the act of sense consisting of a hindrance of vital motion. A creature experiencing a hindrance of vital motion will try to counteract it, typically by retreating from the object of sense. Aversion consists of the small inner movements that initiate the evasive action, just as 'appetite' names the internal beginnings of approach behaviour.

The pursuit of pleasure and the avoidance of pain are the basic drives recognized by Hobbes' psychology, and they determine the systems of valuation of different individuals. The individual takes as good what it has learned to pursue and regards as bad what it has learned to avoid. In developing a system of valuation, a creature is not discovering an objective distinction in nature between things that are good and things that are bad. Nothing is good or bad independently of its effects on creatures, and the effects may vary from creature to creature. At most, things are good or bad *to* individuals, not good or bad 'simply and absolutely'. In the same vein, Hobbes denies that in the sphere of good and bad things there is one that is the highest and whose attainment constitutes happiness. Instead, there are many different goods for many different individuals. Becoming happy in life is not a matter of being successful in the pursuit of one favoured good, but of being continually successful in the pursuit of many.

Hobbes' account of the constraints on the pursuit of human happiness is the connecting link between his theory of the motions of the mind and his moral and political philosophy proper. To attain happiness, people need to know what goods to pursue and how to pursue them. But in the absence of a science of good and evil, pleasure is their main criterion of the good, displeasure the main criterion of bad. Both pain and pleasure, however, are unreliable guides to the good and bad. A person may find a thing pleasant on one occasion and call it 'good', only to change their mind later. Two people can react differently to the same thing, so that it produces pleasure in one and pain in the other, and is called 'good' and 'not good' simultaneously. Pleasure biases judgment in favour of the nearer and more intense good, even if the cost of pursuing this good is displeasure later, and so on. Part of the correction to these distortions is to judge the good of various things not by how they feel when they are enjoyed or shunned, but by the consequences of enjoying or shunning them. If the costs of the consequences outweigh the present benefits, then a supposed good may be merely an apparent good. Again, if someone detached from the pursuit or avoidance of a thing can judge it good or bad, then it may really be so; while if no-one else can see the attraction or repugnance, it may be illusory. Hobbes thinks only science can supply knowledge of the consequences of actions needed to counterbalance valuations derived from pain and pleasure; and he thinks science does not come naturally to people. Abiding by the value judgments of arbitrators does not come easily either, since people are attached to their valuations and unwilling to lose face by deferring to the judgments of others.

6 Politics: the state of nature

Despite the inconsistency in individual value judgments over time, and between the value judgments of different people at the same time, Hobbes thinks that there are some evils that are so large, and that interfere so markedly with everyone's pursuit of happiness, that practically no-one would knowingly pursue a course of action that resulted in them. War is such an evil, and Hobbes thinks he can show that if everyone makes themselves their own judge of what to pursue in the name of happiness, everyone will be involved in war. His argument to this conclusion is at the same time an argument for people to be guided by a judgment other than their own about what is best for them, the judgment of an existing civil power if they live in an existing commonwealth, the judgment of an as-yet-to-be designated civil power if they live outside any commonwealth.

The argument for the inevitability of war starts with assumptions about what is useful to the achievement of any goal. What is useful, no matter what good is being pursued, no matter whether the good is real or merely apparent, is power – that is, present means to future ends. 'Power' covers the physical capacities of individual agents, and also friends, riches and reputation. Not only is power in any form useful, but there can never be, according to Hobbes, too much power at the disposal of an agent in the nature of things. The reason is not that each agent naturally has an insatiable hunger for power, but that each agent is in competition with other agents for other goods, and any advantage one competitor temporarily has over another can, in principle, be overcome. The naturally strong can be toppled by a number of weak people who join forces; the man who has no enemies can be made into an object of hate with a well-judged campaign of character assassination; the wealthy can be robbed or swindled of their riches, and so on. Not only is it useful to acquire more and more power, but people cannot be blamed for doing so if all that organizes their activity in life is the pursuit of felicity.

Felicity is continual success in one's undertakings, whatever they may be. If what one undertakes is to do down one's competitors, then any means that helps to achieve it will be permissible. Or if, as is more likely, one aims at something else, doing down one's competitors can still often promote one's goal. Even the moderate man who wants only a small share of the good life can have reason to resort to foul means if he thinks he will lose everything by playing fair with rivals. And he cannot be sure he does not risk losing everything if he plays fair. In general, the goal of felicity requires one to try to get an advantage and keep it. Disabling others is a

means of keeping the advantage; the outright elimination of competitors is even surer. Because these facts can be discovered by everyone, everyone who pursues felicity must bargain for severe insecurity and even worry about survival. Struggling for survival is far removed from felicity, but the pursuit of felicity, no holds barred, can quickly turn into a struggle for survival. Or to put it Hobbes' way, in the state of nature, people who pursue felicity are in a condition of war.

The argument does not depend on the idea that every human being is naturally selfish. It is true that in *De cive* Hobbes paints an unflattering picture of ordinary human behaviour, emphasizing the tendency of people to look out for themselves, to say one thing to other people's faces and another thing behind their backs, the tendency to think very well of their own opinions, but poorly of the views of others, and to fight over trivialities. This is all ordinary human behaviour, but it is not the behaviour of absolutely every human being. That it is so ordinary is enough, in Hobbes' view, to overturn the Aristotelian idea that human beings are by nature fit for society, but he is not claiming that human beings are uniform, or that their behaviour is uniformly antisocial. Hobbes recognizes a variety of temperaments in human beings, and his state of nature encompasses the vainglorious as well as the moderate. The vainglorious will seek to dispossess others because having more than anyone else is an end in itself. Moderates will go on to the attack because they want only a little and fear that the greedy will take even that. Others again will be at odds because they want something that cannot be shared. Whatever the cause, the general effect will be insecurity, and with insecurity goes many unattractive things – not only feelings of fear, but loss of society, loss of production, loss of technology, loss of art, loss of everything that enables human beings to rise above a life of bare subsistence and savagery. Life in the state of war is, in Hobbes' famous phrase, 'solitary, poor, nasty, brutish, and short'.

Is there no such thing as virtue to keep people from pursuing felicity ruthlessly? Hobbes thinks that precepts enjoining the moral virtues – what he calls 'the laws of nature' – are discoverable even in the state of nature, but people are not morally obliged to act on them if they run the risk of dying as a result: the most basic law of nature is to preserve oneself, and there is an inalienable 'right of nature' to be one's own judge of how to secure one's own preservation and wellbeing. This right may be laid down in the interest of self-preservation, but never at the cost of self-preservation. So if one has reason to think that others will take advantage of one's keeping agreements, or of showing gratitude, of not being judge in one's own cause, of being forgiving and so on through the rest of the virtues, one is not obliged to behave in those ways. One is not obliged to act in a way which will advertise one's vulnerability to the unscrupulous. It is enough that one is willing to behave virtuously if it is not too dangerous.

7 Politics: the commonwealth

The answer to the problems of life in the state of nature is an agreement by most in it to delegate their right of nature to a person, or body of persons, empowered to secure the many against physical attack and against the severe deprivations of the state of nature. That person or body of persons is empowered by a collective submission of the wills of the many to the will of the one or few. The many agree to be guided in their behaviour by the laws of a sovereign, on the understanding that this is a more effective way of securing their safety than individual action in the state of nature. The many lend their wills to the sovereign both as potential enforcers of the law against lawbreakers and as an army of defence against foreign invasion. They lend their wills by doing only what is permitted by the sovereign's law and refraining from what the law prohibits. The law in turn expresses the sovereign's judgment regarding who should own what, who should teach what, how trade may be conducted, how wars should be waged, who should be punished and by what method of punishment, and who should be rewarded and the scale of the reward given.

The sovereign's judgment prevails because it, uniquely in the commonwealth, is still allied to a right of nature. Everyone who is subject to the sovereign thereby delegates their right of nature to the sovereign, but not in return for any forfeit or transfer of right by the sovereign himself. It is true that the commonwealth dissolves – that the obligation not to retract the right of nature lapses – if the sovereign is not able to secure the many against life-threatening incursion. But short of a reversion to the state of nature, the state in the person of the sovereign has a claim to expect the compliance of the many. The many owe it to one another to comply, because they agree between themselves to be law-abiding in return for safety if everyone else is law-abiding. They also owe it to the sovereign, at least for the time that he succeeds in making and keeping the peace, because they voluntarily and publicly submit to the sovereign, signifying to him that they will do what he decrees should be done for their safety.

Hobbes' idea that the sovereign's law can justly reach into every sector of public life had clear

application to the questions being debated during the Civil War period in England. Those who complained that it was wrong for Charles I to appropriate property, to billet troops at will, to raise taxes without the consent of parliament, were given a theory that legitimized those actions. According to the theory, the limitations on a king's powers indicate that a state of nature, with its potential for open war, still prevails. Either the powers of government are separated (in which case the contention between, say, king and parliament reproduces the contention between individuals in the pre-political condition), or else the powers of government are not separated, but are limited by the rights of the subjects (in which case the right of nature has not really been transferred, and people are still liable to prefer their own judgment about what is best for them to the judgment that they have agreed to be guided by, with the same potential for slaughter).

Hobbes' theory permits the sovereign to regulate public life very stringently, but his message to sovereigns – there is no doubt that *Leviathan* in particular was intended to be read by heads of state – was not that it was *wise* to regulate public life very stringently. To begin with, there were limits to what laws could do: belief could not be commanded, so a certain tolerance of freedom of thought was inevitable. Again, people could not be expected to risk their lives in order to obey the law, as that would leave them no better off in the state than outside it. So laws that impoverished people to such an extent that they were starving, having to steal in order to live, were ill-conceived. Likewise forced military service, if it were likely to lead to death, might reasonably be seen as unacceptable according to the terms of Hobbes' social contract. Even a regime of law that secured most people from theft and common assault, but that confiscated all income above a measly minimum, could be seen as a failure by the sovereign to come up with what the many bargained for in entering the state. What the many bargain for is safety and, as Hobbes explains in chapter 30 of *Leviathan*, 'safety' signifies more than a 'bare preservation': it means a modicum of well-being over and above survival.

The arguments from prudence against over-regulation by the sovereign are also arguments against iniquitous practice by the sovereign. Hobbes distinguishes between iniquity and injustice. The sovereign does no injustice to his subjects if he decides to claim as his own all the land in a particular county or all the houses in a village: in creating the sovereign, his subjects give him the power to decree who is the owner of what. For all that, the sovereign may act iniquitously in the sense that he allows his own appetites and interests to count for more than those of anyone else, and so makes himself, for selfish reasons, the owner of more land than anyone else. There is a law of nature against iniquity, and therefore a law that decrees that the sovereign has to *try* to be equitable. But efforts are one thing; actual behaviour is another. The law of nature is not binding on the sovereign's behaviour, since he retains the right of nature and is authoritative about what to do for the best. If, in his opinion, it is for the best to behave iniquitously, then no other free agent, still less one of his subjects, can blame him for behaving accordingly. But the fact that his iniquitous acts are in this sense blameless does not mean that they are wise. If appropriating everyone's land makes people rebellious, albeit unjustly rebellious, then appropriating other people's land may have greater costs than benefits: it is subversive of the sovereign's power, which depends on the willingness of others to obey him.

Regarding the practice of religion, the relationship between Church and state is a central preoccupation of *Leviathan*. Hobbes insists there that it is for the sovereign to decide whether people can join together for purposes of worship – that is, whether a given church can lawfully exist in the commonwealth. And he appears not to have been in favour of the establishment of a plurality of churches:

> But seeing a Common-wealth is but one Person, it ought also to exhibite to God but one Worship; which then it doth, when it commandeth it to be exhibited by Private men, Publiquely. And this is Publique Worship; the property whereof, is to be *Uniforme*: For those actions that are done differently, by different men, cannot be said to be a Publique Worship. And therefore, where many sorts of Worship be allowed, proceeding from the different Religions of Private men, it cannot be said there is any Publique Worship, nor that the Commonwealth is of any Religion at all.
> (Hobbes [1651] 1839 III: 354)

He goes on to say that 'whereas there be an infinite number of Actions and Gestures, of an indifferent nature; such of them as the Common-wealth shall ordain to be Publiquely and Universally in use, as signes of Honour, and part of Gods Worship, are to be taken and used for such by the Subjects'. It is hard to gather from these passages even tacit approval for a pluralistic form of national religious life. On the contrary, it is strongly implied that unless all members of the commonwealth worship in the same way, it will be doubtful not merely which religion the commonwealth observes but whether it observes any. It is as if Hobbes thinks that in a babble of different religious rites there will be

no clear sign of honour from the commonwealth to God. For a clear signal to be sent, the same thing must be transmitted by everyone in the commonwealth. This 'clear-signal' justification for uniformity is not as anti-tolerationist as a justification that holds that all but the appointed religious rites are idolatrous, but it lends support all the same to a highly restrictive form of public religious worship.

As chapter 12 of *Leviathan* shows, Hobbes was aware that people living together but worshipping differently could ridicule or belittle one another's ceremonies and come into conflict. This is another reason for the secular authority to regulate public worship. It is also a reason for worshippers to take religious ceremony out of the public arena altogether, and preserve their differences in private. Hobbes has no quarrel with this sort of privatization of religious practice, so long as it is thoroughgoing: driving it out of the public arena means driving it well out. To obviate regulation, worship must be not only be private (that is, practised openly by a private person) but practised by a private person in secret. As Hobbes says in chapter 31 of *Leviathan*, private worship 'when secret, is Free; but in the sight of the multitude, it is never without some restraint, either from the Laws, or the opinion of men, which is contrary to the nature of Liberty'.

Not only actions required by religious rites can be driven underground if they might disturb the peace; freedom of action in matters indifferent to religion can also be open to regulation, as chapter 31 of *Leviathan* makes clear. Arguably it is indifferent whether prayers are said in Latin or in English; arguably it is indifferent whether services are conducted by married or by celibate men; but notoriously, these are things that people look askance at or insist upon, and about which they can come to blows. For this reason, if for no other, there is a reason for the sovereign to declare what the language shall be, and who shall preside at services.

What is in the sight of the multitude and in the control of the religious is one thing; what is out of sight and uncontrollable is another: 'Internal faith is in its own nature invisible, and consequently exempted from all humane jurisdiction', Hobbes says in chapter 42 of *Leviathan*. Humane jurisdiction is not just secular jurisdiction, but also that of a body charged by a church with the inquisition of believers. Beliefs in general are not subject to the will he says in *De Politico Corpore*, a pirated edition of part two of the *Elements of Law* (1839 IV: 339). And although salvation depends on believing some things and not others, it is hard to be sure which things have to be believed beyond an uncontroversial minimum. For all of these reasons Hobbes is against the policing of religious belief, and against preferment for any one creed. It is in connection with the policing of belief rather than religious practice that his views come close to those of Independents, who in seventeenth-century England favoured a relatively loose, relatively tolerant organization of religious life, in particular a life outside a unitary Church of England. For when he appears in *Leviathan* (chapter 47) to side with the Independents in the Primitive church it is over each person deciding whose preaching to follow, not over many different religions being openly practised ([1651] 1839 III: 695). And in countenancing a variety of religious persuasions Hobbes is not so much showing tolerance as denying the importance to civil order of what goes on below the threshold of visible action.

8 Problems with Hobbes' political theory

In order to legitimize the powers of sovereigns, Hobbes invites his readers to think of sovereigns and states as the creations of free, self-interested people. The condition of subjection to a sovereign, even if it is not entered into by an original contract, can nevertheless be freely endorsed by each subject, since there is a good argument from self-interest for the condition. The argument says that the alternative to subjection is a dangerous chaos, which is infinitely worse than an intrusive but protective civil power. This is the argument directed against people who are already subjects; is the same argument effective when directed at people who do not yet belong to a state, who are in a state of nature? The issue can be sharpened by pointing out that the process of trading the state of nature for the commonwealth involves each person giving something now for the sake of a benefit later. Each person agrees to lay down their right of nature if everyone else will do likewise for the sake of peace. Granting that the condition of peace is better for each than the condition of war, is it not even better for anyone who can get away with it, to retain their right of nature while others give away theirs? Is it not better to pretend to lay down that right and then to take advantage of those who genuinely do so? If the answer to this question is 'Yes', how can the best outcome, from the point of self-interest, be one in which everyone performs and lays down their right of nature?

The question is taken up in a famous passage in chapter 15 of *Leviathan* where Hobbes replies to the fool who pretends that there is no such thing as justice. Commentators have likened it to the question posed by 'prisoners' dilemmas' where, for example, the outcome that would be best for each of two prisoners is for the other to confess and solely take a punishment for a crime, but where it

turns out to be rational for each to confess and receive a punishment less severe than the maximum. The question is how this 'lesser' outcome can be the better one. In the case of the opportunistic non-performer of covenants discussed by Hobbes, the answer is that there is more security in the performance than in the non-performance of covenants. Someone who takes advantage of another's laying down the right of nature can only do so once and expect to get away with it. And the temporary advantage they gain may in any case not counterbalance what they will lose by being opposed by all those whose trust is threatened or betrayed.

Another problem with Hobbes' theory turns on the supposed moral urgency of each person's laying down the right of nature. Hobbes thinks that the biggest threat to the stability of states is the existence of too much scope for private judgment. The more each person is entitled to think for themselves in matters of wellbeing, the worse it turns out for everyone. This implication is supported in Hobbes' theory by a supposedly scientific understanding of the diversity of the passions and the way that the passions get the better of judgment in human beings. By delegating their power of judgment to someone who is not affected by the individual passions of the people ruled over, people actually get access to a more effective (because more dispassionate) means of securing themselves than their own individual judgments. But, by the same token, they forgo any intellectual contribution to public life. They function in the state not as citizens in the full sense but as subjects only: political life for the many consists solely of submission to law. It is by their passivity rather than by the application of their powers of judgment that people promote the public good. This may have seemed persuasive in a time when the Biblical example of Adam and Eve would have been widely understood to illustrate the dangers of private judgment of good and evil, but to contemporary sensibility it verges on the paranoid. In fact, Hobbes' point is not quite that the judgments of human beings about their well-being can never be trusted, but rather that their *prescientific* judgments cannot be trusted. Prescientifically, people are moved by their feelings of pleasure and displeasure to call things 'good' and 'bad' – few have either the resources or the circumstances to be taught any better. But there is a better conception to be inculcated: Hobbes indicates that it consists of showing how things that are genuinely good, as opposed to pleasant, promote peace or self-preservation, while things that are genuinely bad, as opposed to unpleasant, are conducive to war and self-destruction.

Hobbes' moral and political philosophy impresses some people because it reconstructs the reasons there are for doing what morality tells us to do as reasons of self-interest. Such reasons are sometimes thought to give a more compelling answer to the question 'Why be moral?' than accounts which connect moral motivation to the recognition of transcendent Forms or to the rationally unobjectionable, or to a category of what is acceptable under conditions of ignorance of biasing considerations. Philosophers who call themselves Hobbesians in our own day sometimes cite this power of basing moral motivation on non-utopian and non-metaphysical types of reasoning as Hobbes' main contribution to moral philosophy. For these philosophers, notably David Gauthier, Hobbes anticipates a kind of scepticism about the pretensions of moral philosophy to find rationally unignorable and inescapable reasons for doing what it tells us to do. The most that moral philosophy can show us, according to this interpretation, is that many of the things that morality asks us to do are in our interest if we care about ourselves, or more about ourselves than others (see Moral motivation).

9 The scientific status of Hobbes' ethics and politics

The main lines of Hobbes' political philosophy include the idea that the commonwealth is a solution to the ever-present threat of war in the passionate make-up of human beings, and that the commonwealth is made by delegating the right of nature to a sovereign power with unlimited power. This summarizes a theory worked out in very great detail, a theory Hobbes always regarded as ushering in the scientific treatment of morals and politics. What made the theory scientific? A number of answers get support from Hobbes' writings. The scientific status of politics is sometimes said to be owed to its derivation, in some sense, from Hobbes' natural science. Again, Hobbes' use in civil philosophy of a method applicable to natural bodies and bodies politic alike is sometimes thought to be crucial to its scientific status. These answers are consistent with some texts but sit uneasily with others. First, although Hobbes thought that there was a way of approaching the principles of morals and politics from a starting point in the workings of sense and imagination (which were treated of by physics), he consistently denied that civil science *had* to be approached by way of physics. In chapter 6 of *De corpore* he says that people entirely innocent of physics, but who enjoy introspective access to their own passionate states, are able to see in themselves evidence for the truth of the theory of human nature in the civil science. Something similar is said in the Introduction to *Leviathan*. In the same vein

there is the explanation of his having been able to publish *De cive*, the third volume in his trilogy, without having first expounded the principles of parts of philosophy that were prior to politics. Hobbes said that this was possible because civil philosophy depended on principles of its own. What ties together all of these remarks is a belief in the autonomy of civil science, a belief that is not seriously called into question by his saying that the two principal parts of civil philosophy were alike in applying a certain sort of method to the investigation of bodies – bodies politic on the one hand and natural bodies on the other.

When Hobbes says that each part of philosophy deals with bodies, he makes clear that the two kinds of bodies are 'very different' from one another. And there is no evidence that 'body', when applied in the phrase 'body politic', is supposed to mean 'space-occupying thing existing without the mind'. In other words, there is no evidence that bodies politic are bodies in any more than a metaphorical sense. Finally, it is not clear that Hobbes thought that the scientific status of his politics was made more credible by an analogy between bodies politic and natural bodies. It is not as if he thought that natural bodies were well-understood scientifically, and that bodies politic might in principle be as well understood if the methods of physics were applied to them. On the contrary, Hobbes always thought that the properties of human artefacts, such as bodies politic, were much better understood than the properties of natural bodies, which had God's inscrutable will behind them.

It would be a mistake, however, to think that civil science for Hobbes was primarily an exercise in the investigation of the properties of bodies. It was an exercise in putting our judgments about what we ought to do on grounds that were far more solid than pleasure and pain. Good and bad were a matter of what conduced or interfered with self-preservation or peace, not how it felt to do or get this or that. The core of Hobbes' civil science is an attempt to recast the precepts of morality – the laws of nature – as instruments of peace, and to show how the ingredients of war are latent in any project for the pursuit of happiness. The scientific status of the doctrine of the laws of nature – the ground of its claim to be called moral philosophy – was its conforming to the pattern of a deductive system, based on two fundamental laws of nature and the rest derivative. Similarly with the deduction of the rights of sovereigns from the goal of peace. The scientific status of the argument for the inevitability of war consisted in its proceeding from principles about the passions. But these principles were by no means the property of physics or physicists; they were available in each person's introspective self-knowledge.

The deductive character of scientific demonstration was often claimed by Hobbes to interfere with its comprehensibility and its persuasiveness. But by the time of *Leviathan* Hobbes thought that he had finally managed to achieve the best of both worlds. In the third and last version of his political philosophy, persuasiveness and scientific understanding were finally married to his satisfaction. The Review and Conclusion of *Leviathan* says as much. Commentators have tried to chart Hobbes' attempts from 1640 to 1651 to balance reason and rhetoric in his political science, and it remains a controversial question whether this is managed in one way before the appearance of *Leviathan*, and managed in a different way in *Leviathan* itself.

According to a recent interpretation, due to Quentin Skinner, Hobbes constructed his civil science with a special awareness of two humanist assumptions: that there were always two sides to any question, and that arguments over what was just and unjust were never more than probable. In connection with the belief in two sides to every question, Hobbes was alive to the dangers of *paradiastole*, the rhetorical figure by which actions of an apparently vicious character are re-described as instances of a neighbouring virtue, and actions of a noble character are re-described unflatteringly. At first, in *Elements of Law* and *De cive*, Hobbes railed against humanism by arguing that 'science' in a preferred sense put certain conclusions *beyond* controversy. Questions within the scope of science would thus *not* have two sides. More, questions of justice lay squarely within the scope of science. That is, according to both *Elements of Law* and *De cive*, they could be settled by syllogistic reasoning from the definition of justice as sticking to the covenants one enters into, in particular, sticking to the covenant that one will abide by the sovereign's laws or commands. Questions about whether actions were expressions of certain other virtues could also be settled definitively, by establishing whether those actions contributed to peace or the preservation of civil order. For all virtues were means to the establishment or preservation of peace, the maintenance of the covenant establishing the commonwealth pre-eminently so. With a science of the virtues – a science deducing precepts corresponding to the virtues from an overarching requirement of seeking peace, Hobbes had a basis for showing which uses of paradiastole led to erroneous moral evaluations.

So much for the early response to paradiastole. The later response is distinguished by new background assumptions about the human capacity of reason. *Leviathan* (ch. 5) stresses that human beings are not born with the ability to reason in a way that will produce science. Nor are they likely to acquire

this ability easily or recognize it in others. Again, a standard human audience cannot be counted upon to be receptive to the sort of reasoning recommended in *Elements of Law* and *De cive*. Not only does it strain attention, but when it is followed, it does not necessarily compel belief. People need to be *willing* to heed its message, and they are unwilling to do so where it goes against or *seems* to go against their interest. Eloquence or rhetoric is needed to catch the attention, keep it and neutralize the resistance of interest to its conclusions. Hobbes is not only supposed to have dropped some of his earlier strictures on rhetoric by the time he wrote *Leviathan*, but actually to have practised the techniques of Cicero and Quintillian in works composed after 1650.

Hobbes probably *did* change his mind about the uses of rhetoric, but the response to paradiastole is not as central to Hobbes' civil science as the interpretation we are considering suggests, and there is more of a separation in Hobbes between the task of a moral science and the production of conclusive-seeming moral and political conclusions for non-philosophers.

Turning first to paradiastole, let us consider the passage from chapter 15 of *Leviathan* that, according to the interpretation we are considering, is central to the understanding of the point of Hobbes' moral science:

> *Good*, and *Evill*, are names that signifie our Appetites and Aversions, which in different tempers, customes and doctrines of men, are different. And divers men differ not onely in their Judgement, on the senses of what is pleasant and unpleasant to the taste, smell, hearing, touch and sight; but also of what is conformable, or disagreeable, to Reason, in the actions of common life. Nay, the same man, in divers times, differs from himselfe; and one time praiseth, that is, calleth Good, what at another time he disperaiseth, and calleth Evill.

What is crucial here is the idea that evaluative terms in each man's mouth signify appetites or aversions – psychological dispositions to pursue or avoid things – and that these appetites and aversions can vary from person to person. Evaluative terms can accordingly also vary in sifgnification, depending on whose mouth they come from, and what that person's circumstances and history are. Although a given pattern of appetite and aversion in one person need not be idiosyncratic – people can agree in appetites and aversions if their constitutions and experiences are similar – the things that naturally determine the pattern of appetite and aversion are inconstant, and so, if evaluations are dictated by appetites and aversions, there need be no firm distinction between good and evil either, and no firm distinction between people's judgements of what they should do and what they should not do. So it is sheer luck if people do not disagree over good and evil or if they do not disagree so heatedly that they come to blows. There is incipient war, in other words, in the facts of how individual appetites and aversions are naturally formed.

Now although the re-description of vicious actions as virtuous and virtuous actions as vicious is undoubtedly one source of inconstancy and possible disagreement in valuations leading to war, it is only one among others. So the question arises why any linguistic device, let alone any so specific as paradiastolic re-description, should have central importance. Why is not any source of inconstancy in evaluations – linguistic *or* psychological *or* physical – as much a concern of Hobbes' moral science as any other? And why is not ambiguity – the fact of a term's having more than one meaning – the politically dangerous linguistic phenomenon *par excellence* rather than paradiastolic redescription? This suggestion certainly agrees with Hobbes' identification after 1650 of the chief defect of moral philosophy before his own – that it told people to do right without setting out a 'certain rule and measure of right' (*De corpore*, ch. 1, vii). It certainly agrees with his repeated denunciations of the use of each person's judgement – private judgement – as the measure of right and wrong.

HOLISM AND INDIVIDUALISM IN HISTORY AND SOCIAL SCIENCE

Methodological individualists such as Mill, Weber, Schumpeter, Popper, Hayek and Elster argue that all social facts must be explained wholly and exhaustively in terms of the actions, beliefs and desires of individuals. On the other hand, methodological holists, such as Durkheim and Marx, tend in their explanations to bypass individual action. Within this debate, better arguments exist for the view that explanations of social phenomena without the beliefs and desires of agents are deficient. If this is so, individualists appear to have a distinct edge over their adversaries. Indeed, a consensus exists among philosophers and social scientists that holism is implausible or false and individualism, when carefully formulated, is trivially true.
